Faced with this apparent theory-experiment discrepancy, theorists sought either to modify Dirac's theory or to propose a new theory, and thus accommodate the experimental results. Hellmann (1935), Halpern and Schwinger (1935), and Winter (1936) offered modifications of the Coulomb potential, each of which had the effect that it "annihilates the polarization effect completely." Although each of the theoretical calculations predicted null results from double scattering experiments, they were not regarded as solving the problem. One might speculate that this was because these modifications had no physical or theoretical underpinning. They seemed invented solely for the purpose of explaining the experimental results.

Experimental work also continued. The situation became even more confused when Rupp (1935) withdrew several of his results on electron scattering This eliminated the most positive results supporting Mott's theory.\1/ In 1937 Richter published what he regarded as the definitive experiment on the double scattering of electrons. He claimed to have satisfied the conditions of Mott's calculation exactly and had found no effect. He concluded that "Despite all the favorable conditions of the experiment, however, no sign of the Mott effect could be observed. *With this experimental finding, Mott's theory of the double scattering of electrons from the atomic nucleus can no longer be maintained.* It cannot be decided here how much Dirac's theory of electron spin, which is at the basis of Mott's theory, and its other applications are implicated through the denial of Mott's theory" (Richter 1937, p. 554). The discrepancy was further confirmed by the theoretical work of Rose and Bethe (1939). They examined various ways of trying to eliminate the discrepancy and concluded that "the discrepancy between theory and experiment remains -- perhaps more glaring than before" (p. 278).

Thus, at the end of 1939 there was a clear discrepancy between Dirac theory, as used by Mott, and the experimental results on the double scattering of electrons. Yet the theory was not regarded as refuted.

Why was this? The reason is that, at the time, Dirac theory, and only Dirac theory, predicted the existence of the positron (a positive electron). This particle had been discovered in 1932 and had provided very strong support for Dirac theory. In comparison with this success, the discrepancy in electron scattering, along with another small discrepancy in the spectrum of hydrogen, just did not have sufficient evidential weight. The unique, and confirmed, prediction of the positron outweighed these discrepancies. It isn't easy to refute a strongly confirmed theory. Neither is it impossible as demonstrated by the histories of both parity nonconservation and CP violation discussed earlier.

Interestingly, it was the experimental results that were wrong. In the early 1940s experimental work showed that the way in which the experiments were performed during the 1930s had precluded the possibility of observing the polarization effects predicted by Mott. In order to avoid problems with multiple scattering the experimenters had scattered the electrons from the front surface of the targets. Unfortunately this made the effects of plural scattering, a few large scatters rather than just one as required by Mott, very large. The symmetric plural scattering swamped the predicted polarization effect. When the experimental apparatuses were changed to eliminate this problem the discrepancy disappeared.\2/ Mott's theory was then supported by the experimental evidence.

We have seen here a classic case of the Duhem-Quine problem and how the physics community attempted to solve it. There was a clear discrepancy between the experimental results and the predictions of a well-confirmed theory. The experiments were redone to check the results, with careful attention to the experimental conditions required by the theory. Theorists checked on whether or not other effects might mask the predicted polarization effect. Other theorists offered competing explanations. Ultimately a solution was found.

Does the fact that Dirac theory was not regarded as refuted even though experiment clearly disagreed with its predictions mean that physicists disregard negative results whenever it suits their purposes? Do physicists really tune in on existing community commitments, as some social constructivists would have it, and overlook negative evidence? The answer is no. There is no indication in this episode that the negative evidence was disregarded. The physics community examined the theory in the light of all the available experimental evidence, weighed its importance, and then made a decision. I note that even though Dirac theory remained relatively unscathed, both experimental and theoretical work continued until the problem was solved. The discrepancy was not hidden from view, nor was it ignored.

Appendix 7: Evidence for a New Entity: J.J. Thomson and the Electron

In discussing the existence of electrons Ian Hacking has written, "So far as I'm concerned, if you can spray them then they are real" (Hacking 1983, p. 23). He went on to elaborate this view. "We are completely convinced of the reality of electrons when we set out to build - and often enough succeed in building - new kinds of device that use various well-understood causal properties of electrons to interfere in other more hypothetical parts of nature" (p. 265).

Hacking worried that the simple manipulation of the first quotation, the changing of the charge on an oil drop or on a superconducting niobium sphere, which involves only the charge of the electron, was insufficient grounds for belief in electrons. His second illustration, which he believed more convincing because it involved several properties of the electron, was that of Peggy II, a source of polarized electrons built at the Stanford Linear Accelerator Center in the late 1970s. Peggy II provided polarized electrons for an experiment that scattered electrons off deuterium to investigate the weak neutral current. Although I agree with Hacking that manipulability can often provide us with grounds for belief in a theoretical entity,[\1/] his illustration comes far too late. Physicists were manipulating the electron in Hacking's sense in the early twentieth century.[\2/] They believed in the existence of electrons well before Peggy II, and I will argue that they had good reasons for that belief.[\3/]

The position I adopt is one that might reasonably be called "conjectural" realism. It is conjectural because, despite having good reasons for belief in the existence of an entity or in the truth of a scientific law, we might be wrong. At one time scientists had good reason to believe in phlogiston and caloric, substances we now have good reason to believe don't exist. My position includes both Sellars' view that "to have good reason for holding a theory is *ipso facto* to have good reason for holding that the entities postulated by the theory exist" (Sellars 1962, p. 97), and the "entity realism" proposed by Cartwright (1983) and by Hacking (1983). Both Hacking, as noted above, and Cartwright emphasize the manipulability of an entity as a criterion for belief in its existence. Cartwright also stresses causal reasoning as part of her belief in entities. In her discussion of the operation of a cloud chamber she states, "...if there are no electrons in the cloud chamber, I do not know why the tracks are there" (Cartwright, 1983, p.99). In other words, if such entities don't exist then we have no plausible causal story to tell. Both Hacking and Cartwright grant existence to entities such as electrons, but do not grant "real" status to either laws or theories, which may postulate or apply to such entities.

In contrast to both Cartwright and Hacking, I suggest that we can also have good reasons for belief in the laws and theories governing the behavior of the entities, and that several of their illustrations implicitly

involve such laws.[4] I have argued elsewhere for belief in the reality of scientific laws (Franklin 1996). In this section I shall concentrate on the reality and existence of entities, in particular, the electron. I agree with both Hacking and Cartwright that we can go beyond Sellars and have good reasons for belief in entities even without laws. Hacking and Cartwright emphasize experimenting *with* entities. I will argue that experimenting *on* entities and measuring their properties can also provide grounds for belief in their existence.

In this section I will discuss the grounds for belief in the existence of the electron by examining J.J. Thomson's experiments on cathode rays. His 1897 experiment on cathode rays is generally regarded as the "discovery" of the electron.

The purpose of J.J. Thomson's experiments was clearly stated in the introduction to his 1897 paper.

The experiments discussed in this paper were undertaken in the hope of gaining some information as to the nature of Cathode Rays. The most diverse opinions are held as to these rays; according to the almost unanimous opinion of German physicists they are due to some process in the aether to which -- inasmuch as in a uniform magnetic field their course is circular and not rectilinear -- no phenomenon hitherto observed is analogous: another view of these rays is that, so far from being wholly aetherial, they are in fact wholly material, and that they mark the paths of particles of matter charged with negative electricity (Thomson 1897, p. 293).

Thomson's first order of business was to show that the cathode rays carried negative charge. This had presumably been shown previously by Perrin. Perrin placed two coaxial metal cylinders, insulated from one another, in front of a plane cathode. The cylinders each had a small hole through which the cathode rays could pass onto the inner cylinder. The outer cylinder was grounded. When cathode rays passed into the inner cylinder an electroscope attached to it showed the presence of a negative electrical charge. When the cathode rays were magnetically deflected so that they did not pass through the holes, no charge was detected. "Now the supporters of the aetherial theory do not deny that electrified particles are shot off from the cathode; they deny, however, that these charged particles have any more to do with the cathode rays than a rifle-ball has with the flash when a rifle is fired" (Thomson 1897, p. 294).

Thomson repeated the experiment, but in a form that was not open to that objection. The apparatus is shown in Figure 14. The two coaxial cylinders with holes are shown. The outer cylinder was grounded and the inner one attached to an electrometer to detect any charge. The cathode rays from A pass into the bulb, but would not enter the holes in the cylinders unless deflected by a magnetic field.

When the cathode rays (whose path was traced by the phosphorescence on the glass) did not fall on the slit, the electrical charge sent to the electrometer when the induction coil producing the rays was set in action was small and irregular; when, however, the rays were bent by a magnet so as to fall on the slit there was a large charge of negative electricity sent to the electrometer.... If the rays were so much bent by the magnet that they overshot the slits in the cylinder, the charge passing into the cylinder fell again to a very small fraction of its value when the aim was true. *Thus this experiment shows that however we*

twist and deflect the cathode rays by magnetic forces, the negative electrification follows the same path as the rays, and that this negative electrification is indissolubly connected with the cathode rays (Thomson 1897, p. 294-295, emphasis added).

This experiment also demonstrated that cathode rays were deflected by a magnetic field in exactly the way one would expect if they were negatively charged material particles.\5/

There was, however, a problem for the view that cathode rays were negatively charged particles. Several experiments, in particular those of Hertz, had failed to observe the deflection of cathode rays by an electrostatic field. Thomson proceeded to answer this objection. His apparatus is shown in Figure 15. Cathode rays from C pass through a slit in the anode A, and through another slit at B. They then passed between plates D and E and produced a narrow well-defined phosphorescent patch at the end of the tube, which also had a scale attached to measure any deflection. When Hertz had performed the experiment he had found no deflection when a potential difference was applied across D and E. He concluded that the electrostatic properties of the cathode ray are either *nil* or very feeble. Thomson admitted that when he first performed the experiment he also saw no effect. "on repeating this experiment [that of Hertz] I at first got the same result [no deflection], but subsequent experiments showed that the absence of deflexion is due to the conductivity conferred on the rarefied gas by the cathode rays.\6/ On measuring this conductivity it was found that it diminished very rapidly as the exhaustion increased; it seemed that on trying Hertz's experiment at very high exhaustion there might be a chance of detecting the deflexion of the cathode rays by an electrostatic force" (Thomson 1897, p. 296). Thomson did perform the experiment at lower pressure [higher exhaustion] and observed the deflection.\7/

Thomson concluded:

> As the cathode rays carry a charge of negative electricity, are deflected by an electrostatic force as if they were negatively electrified, and are acted on by a magnetic force in just the way in which this force would act on a negatively electrified body moving along the path of these rays, I can see no escape from the conclusion that they are charges of negative electricity carried by particles of matter. (Thomson 1897, p. 302)\8/

Having established that cathode rays were negatively charged material particles, Thomson went on to discuss what the particles were. "What are these particles? are they atoms, or molecules, or matter in a still finer state of subdivision" (p. 302). To investigate this question Thomson made measurements on the charge to mass ratio of cathode rays. Thomson's method used both the electrostatic and magnetic deflection of the cathode rays.\9/ The apparatus is shown in . It also included a magnetic field that could be created perpendicular to both the electric field and the trajectory of the cathode rays.

Let us consider a beam of particles of mass m charge e, and velocity v. Suppose the beam passes through an electric field F in the region between plates D and E, which has a length L. The time for a particle to pass through this region $t = L/v$. The electric force on the particle is Fe and its acceleration $a = Fe/m$. The deflection d at the end of the region is given by

$d = \frac{1}{2} at^2 = \frac{1}{2}(eF/m)L^2/v^2$

Now consider a situation in which the beam of cathode rays simultaneously pass through both *F* and a magnetic field *B* in the same region. Thomson adjusted *B* so that the beam was undeflected. thus the magnetic force was equal to the electrostatic force.

$evB = eF$ or $v = F/B$.

This determined the velocity of the beam. Thus, $e/m = 2dF/B^2L^2$

Each of the quantities in the above expression was measured so the *e/m* or *m/e* could be determined.

Using this method Thomson found a value of *m/e* of $(1.29 \pm 0.17) \times 10^{-7}$. This value was independent of both the gas in the tube and of the metal used in the cathode, suggesting that the particles were constituents of the atoms of all substances. It was also far smaller, by a factor of 1000, than the smallest value previously obtained, 10^{-4}, that of the hydrogen ion in electrolysis.

Thomson remarked that this might be due to the smallness of *m* or to the largeness of *e*. He argued that *m* was small citing Lenard's work on the range of cathode rays in air. The range, which is related to the mean free path for collisions, and which depends on the size of the object, was 0.5 cm. The mean free path for molecules in air was approximately 10^{-5} cm. If the cathode ray traveled so much farther than a molecule before colliding with an air molecule, Thomson argued that it must be much smaller than a molecule.[\10/]

Thomson had shown that cathode rays behave as one would expect negatively charged material particles to behave. They deposited negative charge on an electrometer, and were deflected by both electric and magnetic fields in the appropriate direction for a negative charge. In addition the value for the mass to charge ratio was far smaller than the smallest value previously obtained, that of the hydrogen ion. If the charge were the same as that on the hydrogen ion, the mass would be far less. In addition, the cathode rays traveled farther in air than did molecules, also implying that they were smaller than an atom or molecule. Thomson concluded that these negatively charged particles were constituents of atoms. In other words, Thomson's experiments had given us good reasons to believe in the existence of electrons.

Supplement to Experiment in Physics

Appendix 8: The Articulation of Theory: Weak Interactions

Radioactivity, the spontaneous decay of a substance, produces alpha particles (positively charged helium nuclei), or beta particles (electrons), or gamma rays (high energy electromagnetic radiation). It was discovered in 1896 by Henri Becquerel. Experimental work on the energy of the electrons emitted in β decay began in the early twentieth century, and the observed continuous energy spectrum posed a problem. If β decay were a two-body decay (for example, neutron $\rightarrow$ proton + electron) then applying the laws of conservation of energy and of conservation of momentum requires that the energy of the electron have a unique value, not a continuous spectrum.\1/ Thus, the observed continuous energy spectrum cast doubt on both of these conservation laws. Physicists speculated that perhaps the electrons lost energy in escaping the substance, with different electrons losing different amounts of energy, thus accounting for the energy spectrum. Careful experiments showed that this was not the case so the problem remained. In the early 1930s Pauli suggested that a low-mass neutral particle, named by Fermi as the neutrino, was also emitted in β decay.\2/ This solved the problem of the continuous energy spectrum because in a three-body decay (neutron proton + electron + neutrino) the energy of the electron was no longer required to be unique. The electron could have a continuous energy spectrum and the conservation laws were saved.\3/

In 1934 Fermi proposed a new theory of β decay that incorporated this new particle (Fermi 1934). He added a perturbation energy due to the decay interaction to the Hamiltonian describing the nuclear system. Pauli (1933) had previously shown that the perturbation could have only five different forms if the Hamiltonian is to be relativistically invariant. These are S, the scalar interaction; P, pseudoscalar; V, vector; A, axial vector; and T, tensor. Fermi knew this but chose, in analogy with electromagnetic theory, to use only the vector interaction. His theory initially received support from the work of Sargent (1932; 1933) and others. There remained, however, the question of whether or not the other forms of the interaction also entered into the Hamiltonian.\4/ In this episode we shall see how experiment helped to determine the mathematical form of the weak interaction.

Gamow and Teller (1936) soon proposed a modification of Fermi's vector theory. Fermi's theory had originally required a selection rule, the change in J = 0, where J is the angular momentum of the nucleus, and did not include the effects of nuclear spin. Gamow and Teller included nuclear spin and obtained selection rules, change in J = 0, ±1 for allowed transitions, with no 0--0 transitions allowed. The Gamow-Teller modification required either a tensor or an axial vector form of the interaction. Their theory helped to solve some of the difficulties that arose in assigning nuclear spins using only the Fermi selection rule. At then end of the 1930s there was support for Fermi's theory with some preference for the Gamow-

Teller selections rules and the tensor interaction.

The work of Fierz (1937) helped to restrict the allowable forms of the interaction. He showed that if both S and V interactions were present in the allowed -decay interaction, or both A and T, then there would be an interference term of the form 1 + a/W in the allowed beta-decay spectrum, where W is the electron energy. This term vanished if the admixtures were not present. The failure to observe these interference terms showed that the decay interaction did not contain both S and V, or both A and T.

The presence of either the T or A form of the interaction in at least part of the beta-decay interaction was shown by Mayer, Moszkowski, and Nordheim (1951). They found twenty five decays for which the change in J was 0, ±1, with no parity change. These decays could only occur if the A or T forms were present. Their conclusion depended on the correct assignment of nuclear spins which, although reliable, still retained some uncertainty. Further evidence, which did not depend on knowledge of the nuclear spins, came from an examination of the spectra of unique forbidden transitions.[\5/] These were n-times forbidden transitions in which the change in nuclear spin was n + 1. These transitions require the presence of either A or T. In addition, only a single form of the interaction makes any appreciable contribution to the decay. This allows the prediction of the shape of the spectrum for such transitions. Konopinski and Uhlenbeck (1941) showed that for an n-times forbidden transition the spectrum would be that of an allowed transition multiplied by an energy dependent term $a_n(W)$. For a first-forbidden transition $a_1 = C[(W^2 - m^2c^4) + (W_o - W)^2]$. The spectrum for ^{91}Y measured by Langer and Price (1949) (Figure 16) shows the clear presence of either the A or T forms of the interaction. The spectrum requires the energy-dependent correction.

Evidence in favor of the presence of either the S or V forms of the interaction was provided by Sherr, Muether, and White (1949)and by Sherr and Gerhart (1952). They observed the decay of ^{14}O to an excited state of ^{14}N, $^{14}N^*$. They argued that both ^{14}O and $^{14}N^*$ had spin 0. This required the presence of either S or V because the decay was forbidden by A and T. (Recall that the Gamow-Teller selection rules specified no 0 to 0 transitions).

Further progress in isolating the particular forms of the interaction was made by examining the spectra of once-forbidden transitions. Here too, interference effects, similar to those predicted by Fierz, were also expected. A. Smith (1951)and Pursey (1951) found that the spectrum for these transitions would contain energy dependent terms of the form $G_V G_T/W$, $G_A G_P/W$, and $G_S G_A/W$, where the G's are the coupling constants for the various interactions, and W is the electron energy. The linear spectrum found for ^{147}Pm demonstrated the absence of these terms (Langer, Motz and Price 1950).

Let us summarize the situation. There were five allowable forms of the decay interaction; S, T, A, V, P. The failure to observe Fierz interference showed that the interaction could not contain both S and V or both A and T. Experiments showing the presence of Gamow-Teller selections rules and on unique forbidden transitions had shown that either A or T must be present. The decay of ^{14}O to $^{14}N^*$ had demonstrated that either S or V must also be present. This restricted the forms of the interaction to STP,

SAP, VTP, or VAP or doublets taken from these combinations. The absence of interference terms in the once-forbidden spectra eliminated the VT, SA, and AP combinations. VP was eliminated because it did not allow Gamow-Teller transitions. This left only the STP triplet or the VA doublet as the possible interactions.

The spectrum of RaE provided the decisive evidence. Petschek and Marshak (1952) analyzed the spectrum of RaE and found that the only interaction that would give a good fit to the spectrum was a combination of T and P. This was, in fact, the only evidence favoring the presence of the P interaction. This led Konopinski and Langer (1953), in their 1953 review article on β decay to conclude that, "As we shall interpret the evidence here, the correct law must be what is known as an STP combination (1953, p. 261)."

Unfortunately, the evidence from the RaE spectrum had led the physics community astray. Petschek and Marshak had noted that their conclusion was quite sensitive to assumptions made in their calculation. "Thus, an error in the finite radius correction of approximately 0.1 percent leads to an error of up to 25% in $C_{1(T+P)}$ [the theoretical correction term]." Further theoretical analysis cast doubt on their assumptions, but all of this became moot when K. Smith[\6/] measured the spin of RaE and found it to be one, incompatible with the Petschek-Marshak analysis.

The demise of the RaE evidence removed the necessity of including the P interaction in the theory of β decay, and left the decision between the STP and VA combinations unresolved. The dilemma was resolved by evidence provided by angular-correlation experiments, particularly that from the experiment on ^{6}He by Rustad and Ruby (1953; 1955)

(a) Angular Correlation Experiments. Angular correlation experiments are those in which both the decay electron and the recoil nucleus from β decay are detected in coincidence. The experiments measured the distribution in angle between the electron and the recoil nucleus for a fixed range of electron energy, or measured the energy spectrum of either the electron or the nucleus at a fixed angle between them. These quantities are quite sensitive to the form of the decay interaction and became decisive pieces of evidence in the search for the form of the decay interaction. Hamilton (1947) calculated the form of the angular distribution expected for both allowed and forbidden decays, assuming only one type of interaction (S, V, T, A, P) was present. He found, for allowed transitions, that the angular distributions for the specific forms of the interaction would be different. A more general treatment was given by de Groot and Tolhoek (1950). They found that the general form of the angular distribution for allowed decays depended on the combination of the particular forms of the interactions in the decay Hamiltonian. For single forms their results agreed with those of Hamilton.

The most important of the experiments performed at this time was the measurement of the angular correlation in the decay of ^{6}He. This decay was a pure Gamow-Teller transition and thus was sensitive to the amounts of A and T present in the decay interaction. The decisive experiment was that of Rustad and Ruby (1953; 1955). This experiment was regarded as establishing that the Gamow-Teller part of the interaction was predominantly tensor. This was the conclusion reached in several review papers on the

nature of β decay. (Ridley 1954; Kofoed-Hansen 1955; Wu 1955). The experimental apparatus is shown in Figure 17. The definition of the decay volume was extremely important. In order to measure the angular correlation one must know the position of the decay so that one can measure the angle between the electron and the recoil nucleus. The decay volume for the helium gas in this experiment was defined by a 180 microgram/cm^2 aluminum hemisphere and the pumping diaphragm. Rustad and Ruby (1953) presented two experimental results. The first was the coincidence rate as a function of the angle between the electron and the recoil nucleus for electrons in the energy range (2.5 - 4.0) mc^2. The second was the the energy spectrum of the decay electrons with the angle between the electron and the recoil nucleus fixed at 180^o. Both results are shown in Figure 18 along with the predicted results for A and T, respectively. The dominance of the tensor interaction is clear. This conclusion was made more emphatic in their 1955 paper which included more details of the experiment and even more data. The later results, shown in Figure 19, clearly demonstrate the superior fit of the tensor interaction.

The Rustad-Ruby result, along with several others, established that the Gamow-Teller part of the decay interaction was tensor and that the decay interaction was STP, or ST, rather than VA. We have seen clearly in this episode the fruitful interaction between experiment and theory. Theoretical predictions became more precise and were tested experimentally until the form of the weak interaction was found. Fermi's theory of β decay had been confirmed. It had also been established that the interaction was a combination of scalar, tensor, and pseudoscalar (STP).

(b) Epilogue. It would be nice to report that such a simple, satisfying story, with its happy ending was the last word. It wasn't. Work continued on angular correlation experiments and the happy agreement was soon destroyed (Franklin 1990, Chapter 3). Things became more complex with the discovery of parity nonconservation in the weak interactions, including β decay. Sudarshan and Marshak (1958) and Feynman and Gell-Mann (1958) showed that only a V-A interaction was compatible with parity nonconservation. If there was to be a single interaction describing all the weak interactions then there was a serious conflict between this work and the Rustad-Ruby result. This led Wu and Schwarzschild (1958) to reexamine and reanalyze the Rustad-Ruby experiment. They found, by calculation and by constructing a physical analogue of the gas system, that a considerable fraction of the helium gas (approximately 12%) was not in the decay volume. This changed the result for the angular correlation considerably and cast doubt on the Rustad-Ruby result.[\7/] The ^{6}He angular correlation experiment was redone, correcting the problem with the gas target, and the new result is shown in Figure 20 (Hermannsfeldt et al. 1958). It clearly favors A, the axial vector interaction. Once again, physics was both fallible and corrigible. This new result on ^{6}He combined with the discovery of parity nonconservation established that the form of the weak interaction was V-A.

Scientific Realism

It is easier to define scientific realism than it is to identify its role as a distinctly *philosophical* doctrine. Scientific realists hold that the characteristic product of successful scientific research is knowledge of largely theory-independent phenomena and that such knowledge is possible (indeed actual) even in those cases in which the relevant phenomena are not, in any non-question-begging sense, observable. According to scientific realists, for example, if you obtain a good contemporary chemistry textbook you will have good reason to believe (because the scientists whose work the book reports had good scientific evidence for) the (approximate) truth of the claims it contains about the existence and properties of atoms, molecules, sub-atomic particles, energy levels, reaction mechanisms, etc. Moreover, you have good reason to think that such phenomena have the properties attributed to them in the textbook independently of our theoretical conceptions in chemistry. Scientific realism is thus the common sense (or common science) conception that, subject to a recognition that scientific methods are fallible and that most scientific knowledge is approximate, we are justified in accepting the most secure findings of scientists "at face value."

1. Introduction

We defined scientific realism above as the common sense (or common science) conception that, subject to a recognition that scientific methods are fallible and that most scientific knowledge is approximate, we are justified in accepting the most secure findings of scientists "at face value." What requires explanation

is why this is a philosophical position rather than just a common sense one. Consider, for example, tropical fish realism -- the doctrine that there really are tropical fish; that the little books you buy about them at pet stores tend to get it approximately right about their appearance, behavior, food and temperature requirements, etc.; and that the fish have these properties largely independently of our theories about them. That's a pretty clear doctrine, but it's so commonsensical that it doesn't seem to have any particular philosophical import. Why is the analogous doctrine about science a philosophical doctrine?

The answer is that -- setting aside skepticism about the external world -- there are no philosophical arguments against tropical fish realism, whereas important philosophical challenges have been raised against scientific realism. The dimensions of scientific realism, understood as a philosophical position, have been largely determined by the responses scientific realists have offered to these challenges. It will be conceptually useful (and approximately historically correct) to see the development of scientific realism as a response to four consecutive challenges, as follows.

1. The Empiricist Challenge: This is the challenge regarding knowledge of unobservable "theoretical" entities raised by logical empiricists and their allies and underwritten by arguments from the underdetermination of theory choice by observational data.
2. The Neo-Kantian Challenge, First Version: This is the challenge raised by Hanson (1958) and Kuhn (1970) who argue from the theory dependence of methods (and, especially, of observation) to the conclusion that a realist conception of the growth of approximate scientific knowledge cannot be sustained, given the semantic and methodological incommensurability (Kuhn's term) occasioned by revolutionary changes in science.
3. The Neo-Kantian Challenge, Second Version: This is the (somehow) related, but (somehow) less relativist conception represented by Putnam's ("internal realist") and Fine's ("natural ontological attitude") critiques of "metaphysical" versions of scientific realism.
4. The "Post-modern" Challenge: This is a challenge (to both realism and empiricism) arising from recent literary, sociological and historical studies in the emerging "science studies" tradition. It is grounded in the conception that such phenomena as science, knowledge, evidence and truth are *social constructions*, in some sense or other which implies that one should reject the idea that scientific practices achieve an approximate representational fit, of some sort or other, between the content of scientific theories and *the world* or *reality*.

We will discuss these challenges in the sections below.

2. The Empiricist Challenge: Knowledge Empiricism and the Underdetermination Argument

It is easy to characterize the basic empiricist underdetermination argument against scientific realism. Call two theories *empirically equivalent* just in case exactly the same conclusions *about observable phenomena* can be deduced from each. Let *T* be *any* theory which posits unobservable phenomena. There

will always be infinitely many theories which are empirically equivalent to *T* but which are such that each differs from *T*, and from all the rest, in what it says about *unobservable* phenomena (for formalized theories, this is an elementary theorem of mathematical logic). Evidence in favor of *T*'s conception of unobservable phenomena ("theoretical entities") would have to rule out the conceptions represented by each of those other theories. But, since *T* is empirically equivalent to each of them, they all make exactly the same predictions about the results of observations or experiments. So, no evidence could favor one of them over the others. Thus, at best, we could have evidence in favor of what all these theories have in common--their consequences about "observables"--we could confirm that they are all *empirically adequate*--but we could not have any evidence favoring *T*'s conception of unobservable theoretical entities. Since *T* was *any* theory about unobservables, knowledge of unobservable phenomena is impossible; choice between competing but empirically equivalent conceptions of theoretical entities is underdetermined by all possible observational evidence. [For an important alternative formulation of the notions of empirical adequacy and empirical equivalence, see van Fraassen 1980; see also Demopoulos 1982.]

Several points about this simple and powerful argument are important.

1. *It needs fixing up*. As it stands, the basic underdetermination argument is fatally flawed. Suppose that *T* is some ordinary middle-sized scientific theory, like, e.g., the laws of Newtonian mechanics. According to the argument as it stands if T^* is some other middle-sized theory empirically equivalent to *T*, then no evidence could favor *T* over T^*, or *vice versa*. For ordinary scientific theories this is wrong. Scientists routinely supplement theories with well established *auxiliary hypotheses* in order to obtain observational predictions from them. [In fact, no observational predictions can be deduced from Newton's laws unless they have been so supplemented, and this is true for lots of fundamental scientific theories; see Kitcher 1982 for a nice discussion.] So, even if *T* and T^* are empirically equivalent, it could still happen that they yield different observational predictions when supplemented by appropriate auxiliary hypotheses, in which case there could be observational evidence favoring one over the other.

So, it is probably best to think of the underdetermination argument as applying, not to "small" theories, but to "total sciences," large-scale conceptions of the world that might represent the total scientific conception of the world at a time. Such a conception would already contain all of the auxiliary hypotheses which were legitimate by its lights, so the problem just mentioned does not arise. In this revised form the underdetermination argument says that--whatever our best scientific conception of the world may be at any given time--we will ever have any evidence that it embodies knowledge of unobservables.

2. *It rests on (a particular interpretation of) an extremely plausible doctrine about factual knowledge*. Traditional empiricism attributed to experience or sensation two different roles: experience was the source of all of our ideas--of the raw material for thinking--and experience was the only basis we have for justifying beliefs abut matters of fact. The first of these doctrines of empiricism has fallen on hard times, but the second doctrine (called *knowledge empiricism* by Bennett 1964) enjoys widespread support. In particular, it is an epistemological doctrine to which almost all scientific realists subscribe. The logical empiricist challenge to scientific realism arises from a quite plausible interpretation of knowledge empiricism according to which what it says is that there can be no evidence which rationally distinguishes

between two empirically equivalent total sciences (call this doctrine the *evidential indistinguishability thesis*, or the *EIT*).

3. *It is part of a selectively skeptical program of anti-metaphysical "rational reconstruction."* The basic aim of the logical empiricists' project was to solve the *demarcation problem*, the problem of distinguishing science (*good*) from "metaphysics" (*bad*), by appealing to arguments like the underdetermination argument. The result was supposed to be that scientific claims are meaningful and knowable (early on, logical empiricists identified these two properties) whereas "metaphysical" claims, because they are about unobservables, are (at least) unknowable and (according to early versions of logical empiricism) meaningless.

Now almost all actual science is conducted largely in a vocabulary consisting mainly of "theoretical terms": terms apparently referring to unobservables. It was definitely not the logical empiricists' project to reject such science. They intended to be selectively skeptical: to be skeptics about "metaphysics" but not about science. So, they embarked on a project of providing "rational reconstructions" of *actual* scientific theories and methods which were designed to eliminate any apparent commitments to knowledge of unobservables while still portraying actual scientific practices as sources of knowledge (see, e.g., Carnap 1932, 1959).

In the case of scientific theories, the basic logical empiricist approaches were variations on the idea of *instrumentalism*, the view that scientific theories were predictive instruments and that the knowledge they represent is limited to what they predict about the observable properties of observables. In the case of scientific methods, strategies for rational reconstruction have not been so easy to formulate. Here's the problem. Almost all of the methods scientists actually use in conducting experimental or observational studies are *theory dependent*: they depend for their justification on knowledge reflected in previously established theories. Kuhn's (1970) discussion of "normal science" makes this point especially clearly, but all of the logical empiricists were acutely aware of it. Moreover, in sciences like physics, chemistry, molecular biology and astronomy, almost all of those methods seem *prima facie* to rest on knowledge of unobservable phenomena (just think about the presuppositions of the design of any experiment in chemistry). What the project of rational reconstruction must show is that (almost) all of these methods can be reconstructed in such a way that their application, as guides to the identification of empirically adequate theories, does not require positing knowledge of unobservables.

4. *The task of rationally reconstructing actual scientific methods has been the most significant challenge facing logical empiricism and related anti-realist approaches*. Instrumentalism and its variants provide a simple reconstruction of the content of scientific theories that pretty exactly fits the requirements of the project of rational reconstruction. The depth of the theory dependence of scientific methods, and the extent to which they seem to depend on knowledge of unobservables, has posed a deeper challenge for logical empiricists and their allies. The fate of operationalism illustrates this challenge. Operationalism was a proposal for rationally reconstructing the use of "theoretical terms" (terms that apparently refer to unobservables) in science by treating those terms as being completely defined in terms of particular operational procedures, thereby eliminating the apparent references to unobservables.

Here’s what operationalism says. For any theoretical term (say, for example, "electron density") we can "rationally reconstruct" the use of that term by treating it as having an *analytic* operational definition in terms of laboratory procedures and instrumentation. So, for example, the operational definition of "electron density" might be given by a sentence of the form

> (*) The electron density in a region, *R*, is given by the value, *x*, if and only if *E* applied to *R* yields the value *x*,

where *E* is an instrument such that -- *prior to rational reconstruction* (but not after) -- scientists would have thought of it as a procedure for measuring electron density.

The analyticity of operational definitions like (*) is essential to the project of rational reconstruction. Operationalism *is not*, for example, the idea that electron density is defined as whatever magnitude instruments of sort *E* reliably measure. On that conception (*) would represent an empirical discovery about how to measure electron density, but -- since electrons are "unobservables" -- that’s a realist conception not an empiricist one. What the project of rational reconstruction requires is that (*) be true *purely as a matter of linguistic stipulation* about how the term "electron density" is to be used.

Since (*) is supposed to be analytic, it’s supposed to be unrevisable. There is supposed to be no such thing as discovering, about *E*,, that some other instrument provides a more accurate value for electron density, or provides values for electron density under conditions where *E* doesn’t function. Here again, thinking that there could be an improvement on *E* with respect to electron density requires thinking of electron density as a real feature of the world which *E* (perhaps only approximately) measures. But, that’s the realist conception which operationalism is designed to rationally reconstruct away.

In actual, and apparently reliable, scientific practice, changes in the instrumentation associated with theoretical terms is utterly routine, and apparently crucial to the progress of science. Scientists routinely replace one instrument with another in order to achieve (as they would say) more accurate measurements of some unobservable magnitude -- often in the light of new theoretical developments -- or to permit measurement of it under conditions for which previous instrumentation was inadequate. According to an operationalist conception, these sorts of modifications would not be methodologically acceptable. Most logical empiricists were not willing to accept this conclusion. After all, they intended to rationally reconstruct the best of actual scientific practice. So most logical empiricists felt compelled to reject operationalism.

Examples such as these made it clear that -- in apparently reliable scientific practice -- scientists behave as though (1) they obtain knowledge of unobservable (as well as observable) phenomena by deploying instruments which (perhaps indirectly) *detect* them, and (2) their theory dependent methodology in these and other matters is informed by knowledge of unobservables as well as of observables. In particular, they appear to improve, or extend the range of, procedures for measuring or detecting unobservable phenomena in the light of theoretical knowledge of those phenomena.

These features of scientific practice stimulated the articulation (largely by philosophers in the empiricist

tradition) of two different but related arguments for scientific realism, to which we now turn our attention.

3. Realist Responses to the Empiricist Challenge: The Senses Extended and Explanations Rehabilitated

3.1 Extending the Senses

The fact that scientists, apparently justifiably, treat certain instruments and procedures as ways of detecting and measuring unobservable (as well as observable) phenomena led several philosophers (see especially Feigl 1956, Maxwell 1962) to adopt what amounts to a non-empiricist (or, perhaps, more flexibly empiricist) understanding of knowledge empiricism according to which (1) the special epistemic role of the senses derives from the fact that they are the only detectors we have built in to our bodies, but (2) the range of phenomena we can detect and measure can be broadened by extending the range of our senses through the use of instruments and procedures whose justification is theory dependent. Thus knowledge of phenomena "unobservable" by traditional empiricists standards is possible. This sort of focus on laboratory detection and manipulation in defense of realism finds perhaps its most energetic expression in the writings of Hacking (see, for example, Hacking 1982).

3.2 Explanation Rehabilitated

The conception that instruments, designed with the help of theoretical understanding, can extend the range of the senses so as to provide information about unobservable phenomena surely has to be a component of any even remotely plausible defense of scientific realism. Still, by itself the idea that instruments can extend the senses is inadequate as a rebuttal to the basic underdetermination argument. Here’s why. The basic idea behind the extending-the-senses approach to defending scientific realism is that -- as scientists’ knowledge of unobservable phenomena improves and as instrumental design becomes more sophisticated -- measurement and detection would become possible for phenomena hitherto beyond the reach of reliable detection and measurement; think of going from light microscopes, to electron microscopes, to x-ray crystallography devices (which can produce images of atomic structures within crystals).

That has to be the realist’s conception, but consider the effect of underdetermination arguments. Suppose that, at some stage in the process of the improvement of theories and instruments, certain phenomena, *D*, posited by existing theories are detectable by the extended senses, but others are not. Let *T* be the total science of the time, and let T^* be a theory empirically equivalent to *T* with respect, not to their observational consequences, but with respect to their consequence regarding the phenomena in *D*. The basic underdetermination argument can be repeated with respect to *T* and T^*, leading to the conclusion that *T* does not reflect any knowledge of phenomena outside *D*. Thus there is no evidential basis for any extension of measurement and detection beyond *D*. Since this argument is applicable at any stage of any

supposed extension of the senses, it challenges -- in the name of knowledge empiricism -- *any* extension of the senses.

3.3 Explanation as Evidential

Considerations such as these seem to have focused the attentions of realists on what we might call *extra-experimental* standards for theory assessment. To see what these are, let's examine the *EIT* mentioned earlier. Why would a knowledge empiricist defend the *EIT*? An obvious answer is that she might think that the only consideration which ever justifies accepting one theory, *T*, over a rival, T^*, is that some prediction about observables obtained from *T* has proven to be true, whereas a prediction from T^* about the same experiment or observation has proven to be false.

But is anything like this right? Pretty obviously -- and pretty obviously by empiricist standards -- no. Here's why. Consider any case in which observations in some set, *O*, provide us with good scientific evidence to accept some theory, *T*, such that *T* applies to an range of observable cases not represented in *O* (that is, consider any case of scientifically justified induction). In any such case there will always be infinitely many pair-wise empirically *in*equivalent theories such that (a) each of them is empirically inequivalent to *T and* (b) each of them is compatible with all the observational data ever collected. This is just the Humean point that induction is not deductively valid. If we have sufficient scientific evidence to justify our accepting *T*, that evidence must justify our rejection of each of these other theories. [Note that this conclusion must be accepted whether one is an empiricist or a scientific realist regarding the interpretation of *T* and its rivals, since the theories in question are pair-wise empirically inequivalent and are empirically inequivalent to *T*.]

Let T^* be one of these rivals to *T*. T^* is empirically inequivalent to *T*, so it would be possible in principle to run a crucial experiment to discriminate between *T* and T^*. But, rational standards for the assessment of scientific evidence dictate that we are justified in rejecting T^* even though no such experiment has been run! So, there must be rational standards for the assessment of scientific evidence *in addition to the standards which say that evidence for or against a theory can be provided by the success or failure of observational predictions derived from the theory*. Let's call these standards *extra experimental*. They solve the equation (!):

> (!) *T*'s observational predictions have been thus far confirmed + *Y* = There is good scientific evidence favoring the empirical adequacy of *T*,
>
> AND, both realists and empiricists agree, they are capable of adjudicating between competing substantive conceptions of the world (because they can adjudicate between empirically inequivalent theories).

So, realists and empiricists agree that it isn't true that rational standards for the assessment of scientific evidence dictate that choice between competing theories must always be based on the results of crucial experiments. Where does that leave the underdetermination argument against knowledge of

unobservables?

Almost all scientific realist responses to empiricist anti-realism in the last three decades can be understood as variations on the idea that the solution to (!) -- which empiricists must agree exists on pain of abandoning selective skepticism for skepticism about induction -- also solves (!!):

> (!!) *T's* observational predictions have been thus far confirmed + *Y* = There is good scientific evidence favoring the (approximate) truth of *T*, even of its claims about unobservables.

Defenses of realism along these lines (see, e.g, Boyd 1983; Byerly and Lazara 1973; Lipton 1993; Miller 1987; McMullin 1984; Psillos 1999; Putnam 1972, 1975a, 1975b) deploy somewhat different resources, but one thing they have in common is that they reflect, and participate in, what might be called the rehabilitation of explanation in recent philosophy of science. An obvious reply to the *EIT* is that it ignores the role of explanation as an evidential standard: perhaps one, among a family of empirically equivalent theories, is to be preferred because it explains observable phenomena better than the others, even though it makes the same observational predictions. The standard logical empiricist treatment of explanation, the deductive-nomological account (see Hempel 1942, 1965; Hempel and Oppenheim 1948), responds by identifying the explanatory power of a theory with its predictive power.

Over the last several decades a great many philosophers have been critical of some aspects or other of this reduction of explanation to prediction (see, e.g., Boyd 1985; Kitcher 1981; Lipton 1991; Kitcher and Salmon 1989; McMullin 1984, 1987; Miller 1987; Salmon 1984, 1989). In the context created by this critical work, the notion of explanation, as an independent component of rational scientific methodology, has been to some extent rehabilitated.

A closely related development is also important. Goodman 1954 drew the attention of philosophers of science to the important point that only some hypotheses, the *projectible* ones, are in the running for confirmation by observations, and that projectibility judgments are in some way or other *a posteriori* judgments informed by previously established theories and practices. What has become pretty clear is that, however they are to be philosophically analyzed, projectibility judgments are in fact judgments of plausibility in the light of previously established theories (Boyd 1999; Lipton 1991, 1993), and that plausibility of the relevant sort is a matter of the sort of unification with those theories which has explanatory import. So, explanation, in its own right, and as an aspect of projectibility judgments, appears to play a crucial role in the assessment of observational evidence for scientific theories.

To a good first approximation, the following characterize the conditions under which observations, *O*, substantially confirm a theory *T*:

1. *T* is projectible (that is, theoretically plausible in the light of the best established science).
2. The observations in *O* either confirm predictions obtained from *T*, or validate explanations based on *T* or both.
3. For each of the projectible alternatives, *A*, to *T* which address the same questions, the observations

in *O* provide evidence against the predictions and/or explanations underwritten by *A*.
4. The observations in *O* were obtained under conditions which embody controls for each of the experimental artifacts or errors of sampling which are suggested by projectible conceptions of the relevant observational or experimental conditions.

The basic strategy of defenses of realism which argue that the solution to (!) -- which empiricists accept -- also solves (!!) involves arguing that the considerations of explanatory power of the sort indicated in characterizations like 1.-4. successfully adjudicate between empirically equivalent theories, so that knowledge of unobservables is sometimes obtained.

3.4 Two Explanationist Strategies for Defending Realism

There is a (very) rough division between two versions of the strategy in question. One strategy, let's call it *local explanationism*, (perhaps reflected in McMullin 1980, 1987; Miller 1987; and Lipton 1993) involves arguing that the relevant explanation-involving, extra-experimental criteria do, in some cases, successfully adjudicate between empirically equivalent theories, so that some scientific knowledge of unobservable phenomena is actual. An alternative approach, the *abductive strategy*, (see, e.g., Boyd 1983, Psillos 1999) treats scientific realism *itself* as a scientific hypothesis which is supported by the fact that it provides the only viable explanation for the such success as methodological principles like 1.-4., above, have as guides to the identification of *empirically adequate* theories. The justification of inductive methods in science is, therefore, provided by scientific realism, understood as itself an *a posteriori* scientific hypothesis.

There are interesting differences between these approaches, and between the various different versions of each, but certain empiricist challenges can be raised against all or most of them. Fine (1984, 1986a) has offered two very significant, and closely related, criticisms of the abductive strategy. First, Fine argues, the strategy begs the question against anti-realist positions by treating scientific explanatory power as carrying evidential weight in philosophy. After all, the dispute between empiricist anti-realists and realists is, in the first instance, a dispute about whether a theory's explanatory power can count in favor of the claims it makes about unobservables. [van Fraassen 1980 makes similar criticisms; he and Laudan 1981 each also challenges the claim that scientific realism provides the best explanation for the reliability of scientific methods in identifying empirically adequate theories.]

Fine's second criticisms is more abstractly epistemological. He points out that, according to the realist who adopts the abductive strategy, the methods of science are to be philosophically justified by appeal to *a posteriori scientific* findings, i.e., by appeal to the scientific realist's scientific explanation for their reliability. This approach, he argues, violates the philosophical requirement that the justification for the methods in a domain of inquiry should be grounded in methods more secure than the methods being justified.

Plainly these criticisms represent serious challenges to the abductive strategy. Importantly, they also challenge *any* version of the local explanationist strategy unless it incorporates an *a priori* (as opposed to

an empirical scientific) defense of the evidential relevance of the explanatory power of theoretical claims about unobservables. There are two reasons to doubt that such an *a priori* defense is available.

In the first place, philosophical defenses of epistemological positions almost always rest, at least in part, on appeals to philosophical "intuitions" regarding particular cases. Although many philosophers regard the deliverances of philosophical intuitions as justified *a priori*, in fact epistemic intuitions about particular cases deliver to us the results of our trained (or, in some cases, untrained) judgments regarding the domain of inquiry in question. They are reliable guides to matters epistemological just in case -- and to the extent that -- the training in question has itself been relevantly reliable (Boyd 1999).

For philosophers of science, the relevant training centrally includes training in the methods and findings of the relevant sciences. Since, "pre-analytically" at least, those methods countenance inductive inferences to explanations involving unobservables, and since the most celebrated findings often incorporate the results of such inductions, a very significant burden of proof would rest on someone who maintained that her philosophical arguments in favor of accepting inductive inferences to explanatory theories about unobservables did not, at least tacitly, rest on intuitions which beg the question against empiricist anti-realism.

Moreover, there are independent reasons to doubt that there could be *an a priori* defense of accepting the results of inductive inferences to the best explanation, *whether or not that explanation posits unobservables*. To a good first approximation, typical scientific explanations offer accounts of the causal mechanisms or processes by which some phenomena are brought about, and scientists evaluate the explanatory power of a theory by trying to assess the likelihood that mechanisms or processes posited by the theory operate to produce the relevant effects. Their judgments in these matters are, almost always, informed by experiments and observations but they are nevertheless highly theory dependent, ordinarily relying heavily on previously established "background" theories concerning the relevant sorts of causal mechanisms and processes (for accounts with this flavor see, e.g., Lipton 1993, Psillos 1999, Boyd 1985). Such judgments are reliable only to the extent that those background theories are relevantly approximately accurate.

In consequence, any defense of the practice of counting the explanatory power of a particular theory as providing evidence in its favor would appear to require a defense of the proposition that the findings of the relevant background sciences are relevantly approximately accurate. While, in some cases, this may be a justified conclusion, its justification could hardly be *a priori* (for an account somewhat more sympathetic to *a prioricity* for certain cases, see Miller 1987). Exactly similar arguments regarding theory dependent judgments of projectibility provide additional *prima facie* support for the same anti-*aprioristic* conclusion (Boyd 1999).

In the light of these challenges, there is a strong case to be made that any defense of scientific realism must rest on a conception according to which both scientific methods *and* methods in the philosophy of science, must lack *a priori* justifications. Such a conception of science, and of the relevant parts of philosophy, would thus be non-foundational and, presumably, naturalistic (see Psillos 1999). [For a somewhat different naturalistic conception, see Kitcher 1993. For an excellent discussion of competing

metaphilosophical conceptions in the philosophy of science and their relation to debates about realism see Wylie 1986.]

3.5 Realism and Approximate Truth

Whether or not the defense of scientific realism requires the adoption of a non-foundationalist conception of knowledge, it almost certainly requires the articulation of a conception of approximate truth. It is central to any plausible realist conception that, at least sometimes, the historical development of scientific theories reflect progress by successive approximation to the truth -- about unobservables as well as about observables, and it is central to arguments for realism that involve the rehabilitation of explanation as an epistemic notion that relevant improvements in approximate knowledge are typically reflected in improvements of method. So, realist philosophy of science relies heavily on the notion of approximate truth.

Laudan 1981 raises against scientific realism (and especially against abductive arguments for realism) the "pessimistic meta-induction." He points out that there are lots of real historical cases in which scientific theories which have been predictively successful and have contributed positively to scientific methodology have not been true, so that the truth of scientific theories need not be posited in order to explain the successes of scientific practice.

The obvious realist reply is that what must be posited is the *approximate* truth the relevant theories (see Hardin and Rosenberg 1982 and Laudan 1984). Articulation of this reply raises important issues, since *any* consistent theory can be represented as approximately true in certain respects, Moreover, as Laudan points out, many of the historically important and methodologically significant theories are, by our current lights, deeply false in some important respects. Efforts to develop an appropriate account of approximate truth in science include Niiniluoto 1987, Oldie 1986, Weston 1992, Boyd 1990.

One novel approach to the problem of approximation is provided by Worrall’s structural realism (Worrall 1994; for a critique see Psillos 1995, 1999). The basic idea here is that the most serious departures from the truth in scientific theories tend to be errors about the *natures* of the basic phenomena rather than about their *structural relations*. In the light of this generalization, the structural realist proposes accepting the claims about causal *structures* (even unobservable ones) posited by well confirmed theories while withholding acceptance from what those theories say about the *natures* of the phenomena so related. To a good first approximation, one might think of structural realism as the view that, for any well established scientific theory, *T*, one should accept the Ramsey sentence obtained from *T* by replacing each theoretical term in *T* by a new variable, and then prefixing, to the resulting open sentence, existential quantifiers over those variables, where the quantification is understood to range over causal structures in nature.

Aside from its importance as a contribution to the literature on approximate truth, structural realism is significant in two other ways. In the first place, it reflects a general tendency in the literature on scientific realism to worry about the extent to which scientific realists must portray scientific knowledge as potentially resolving genuinely *metaphysical* questions. Putnam’s internal realism and Fine’s natural

ontological attitude (discussed below) may be seen as important ontologically deflationary approaches to this question.

The other significance of structural realism lies in the fact that the distinction upon which it relies -- that between causal structures and natures -- may have been, in a certain sense, challenged by philosophers like Shoemaker (1980) who hold that properties, magnitudes, states and the like are defined by their contributions to the causal powers of things. It is an interesting question whether approaches to metaphysics like Shoemaker's are compatible with the approaches to approximation informed by structural realism.

4. The Neo-Kantian Challenge: First Version

Hanson (1958) and, especially, Kuhn (1970 -- first published 1962; see Scheffler 1967, Shapere 1964 for early discussions) raised significant challenges to scientific realism, arguing from the theory dependence of methods (and, especially, of observation) to the conclusion that a realist conception of the growth of approximate scientific knowledge cannot be sustained The intellectual impact of their work in the philosophy of science has been very different from the impact it has had in the rest of the humanities and in many of the social sciences. In the later disciplines the impact of Kuhn, especially, has been to underwrite the sort of anti-realist "postmodernism" discussed later in this essay. In the philosophy of science, by contrast, the impact of Hanson and Kuhn has been mainly to stimulate the articulation of *naturalistic* or *causal* conceptions of reference and *essentialist* conceptions of the definitions of scientific kinds and properties. [I am here presenting what might be thought of as the "standard" conception of Kuhn's position and of responses to it. There has been a recent revival of interest in Kuhn among analytic philosophers and others, and alternative readings of Kuhn are possible (see, e.g., Hoyningen-Huene 1993 and the papers collected in Hoyningen-Huene and Sankey 2001). Whatever the merits of less standard interpretations of Kuhn, it was the standard conception of his arguments that occasioned the realist responses discussed here.]

That arguments proceeding from the theory dependence of scientific methods and of measurement should have been deployed *against* realism is initially surprising. After all, most of the significant arguments *for* scientific realism emphasize theory dependence. Moreover, Kuhn's discussion of what he calls *normal science* seem to have exactly anticipated the abductive argument for realism discussed above. He insists that the success of research in normal science is explained, in significant part, because scientific practitioners have, as a result of their understanding of the paradigmatic theory, a quasi-metaphysical knowledge of the basic (and often unobservable) causal factors involved in the phenomena they study.

Where Kuhn's account departs from a realist conception of the growth of approximate knowledge is in his treatment of what he calls *scientific revolutions*. Although most empiricist philosophers of science had recognized the theory dependence of scientific methods even before the work of Hanson and Kuhn, it was Hanson's and Kuhn's work which made it clear that accepting the theory dependence of scientific methods raise the possibility of *incommensurability* between competing scientific theories (or *paradigms*): the possibility that in science there might be disagreements between theoretical perspectives

such that there do not exist methods for their resolutions which are both *rational* and *fair* (to the competing positions).

What each author claimed was that this situation had actually obtained in important historical cases where, according to a realist perspective, one might think that the rational application of scientific methodology had resulted in the replacement of one theory by a more nearly accurate one. What was especially striking -- and challenging to a realist conception -- was Kuhn's claim that among the "scientific revolutions" where this had occurred was the transition from Newtonian mechanics to special relativity at the beginning of the 20th century.

What is important in understanding the realist response to Kuhn's claim about this particular historical case is that there are lots of experimental results (like, e.g., those which are ordinarily understood to reflect the increase of mass of particles in a cyclotron) such that they certainly look like cases in which a methodology -- including measurement procedures -- which is acceptable by both Newtonian and relativistic standards adjudicates in favor of the relativistic conception. Lots and lots of relativistic effects are such that they can be, apparently, detected and measured using instruments whose design begs no questions against either of the competing "paradigms." The transition from Newtonian mechanics to special relativity certainly looks like a textbook case of rational progression from, one theory to an even more accurate one.

Against this picture Kuhn argues that no such successive approximation occurred because Newtonian mechanics and relativity theory do not share a common subject matter regarding which the latter is a better approximation than the former. For example -- he argues -- the term "mass" as it occurs in Newtonian mechanics does not refer to the same magnitude as does the term "mass" in relativistic mechanics because "Newtonian mass is conserved; Einsteinian is convertible with energy. Only at low relative velocities may the two be measured in the same way, and even then they must not be conceived to be the same (102)."

In giving this remarkable argument Kuhn was tacitly relying on a conception of the referential semantics of scientific terms probably derived from the work of Carnap (see Carnap 1950; there are important controversies about the proper interpretation of Carnap -- see, e.g., Friedman 1987, 1991 -- but they are irrelevant to our story). The conception in question is a version of the standard empiricist "descriptivist" conception that the referent of a term is picked out by a description which constitutes the analytic definition of the term in question. According to the version Kuhn relies on, the analytic definition of a scientific term is provided by the most basic laws containing the term. Thus, as the example of "mass" illustrates, any change in the fundamental laws involving a scientific term must involve a change in referent (or reference *failure*, a possibility Kuhn 1970 does not discuss).

4.1 "Causal" and Naturalistic Theories of Reference

What was important for the development of realist philosophy of science was the fact that most philosophers of science were, at least tacitly, themselves inclined to some version of analytic

descriptivism. The anti-realist consequences which Kuhn (and Hanson) derived from descriptivist conceptions let to the articulation by realists of alternative theories of reference. Characteristically, these theories followed the lead of Kripke (1971, 1972), whose work was mainly concerned with the semantics of modality, and Putnam (1972, 1975a, 1975b), whose work was mainly concerned with issues in the semantics of scientific terms. Each of them advocated a "causal" theory of reference according to which the reference relation between a term and its referent was a matter of there being the right sort of (chain of) causal relation(s) between uses of the term and (instances of) its referent. Numerous variations on this *naturalistic* theme -- some assigning importance to descriptive elements as well as causal relations in the establishment of reference -- have been proposed (see, e.g., Boyd 1999, Dretske 1981, Enç 1976, Field 1973, Kitcher 1992, Miller 1987, Papineau 1987, 1993, Psillos 1999). It is by now pretty well accepted that some departure from analytic descriptivism, involving some causal elements, is a crucial component of a realist approach to scientific knowledge.

4.2 Realism and the Revival of Essentialism

Kuhn's analytic descriptivism assigns to the analytic definition of a scientific term the role of fixing its referent. Once that role is assigned to other ("causal," "naturalistic") features of term use, it becomes possible to explore the issue of non-analytic *a posteriori* definitions of the kinds, magnitudes, etc. to which scientific terms refer. The work of Kripke and Putnam just cited gave rise to a class of theories according to which scientific kinds, etc. have real rather than nominal definitions ("real essences" rather than "nominal essences" in the sense of Locke 1689). The paradigm example is that the real definition, or essence, of water is described by the formula "H_2O". It is by now a standard feature of realist conceptions of science that they incorporate some version or other of the idea that scientific kinds, categories, etc. (*natural kinds*) possess such real definitions (for interesting discussions of the development of this realist conception with special reference to biological kinds see Wilson 1999a, 1999b).

The idea that natural kinds possess such definitions has been consistently linked, in the realist literature, to discussions of the *projectibility* of predicates and hypotheses (Goodman 1954, Quine 1969). Only by reference to kinds (etc.) with real rather than nominal definitions -- only by, *in some sense or other*, "cutting the world at its (*a posteriori* defined) joints" -- are we able to fit our language use to the world in such a way as to make reliable induction and explanation possible (Boyd 1999; Psillos 1999; Putnam 1972, 1975a, 1975b; Sismondo 1996; Wilson 1999b).

One further point about real essences is important. The stock example of a real definition (H_2O for water) might suggest that real definitions of scientific kinds (etc.) must, like logical empiricists' ideal nominal definitions, specify necessary and sufficient conditions for kind membership. In fact, examination of cases in those sciences which study complex phenomena indicate that some natural definitions may consist of families of imperfectly "clustered" properties, with the result that the kinds they define do not have precisely determinate boundaries (Boyd 1999, Wilson 1999b; but see also Hacking 1991a, 1991b). Realism may imply that there is, in that sense, vagueness in nature (contrast Putnam 1983).

4.3 The Metaphysics of Social Construction

Kuhn tacitly adopts a semantic conception according to which the most basic laws in a paradigm are *exactly* true by linguistic convention. He also claims that such laws provide quasi-metaphysical knowledge of basic causal factors. His claim that these laws are exactly true is what leads him to conclusions about the (semantic) history of recent physics which are *prima facie* implausible, and it is this feature of his semantic conception against which causal or naturalistic theories of reference are mainly directed.

The example of the semantics of the names of fictional characters indicates that the linguistic conventions operating in fiction make it possible to establish it *by convention* that certain claims about a character are *approximately* true without thereby establishing their *exact* truth. Versions of Kuhn's social constructivist position could, therefore, be formulated according to which the establishment of a paradigm imposes *by convention*, on the phenomena scientists study, a quasi-metaphysical structure which makes the central laws of the paradigm approximately (but not necessarily exactly) true.

Although Kuhn never considered this version of constructivism, it fits well with the tradition of anthropological relativism to which Kuhn's position is often assimilated. It is not refuted by arguments for causal or naturalistic theories of reference, nor does it entail wildly implausible claims about incommensurability in recent science. It is, however, pretty clearly an anti-realist position -- one which has resonances with the sorts of "postmodern" anti-realism discussed later in this essay. A realist rebuttal to it is available if one makes explicit, and defends, a piece of common, and philosophical, sense about the metaphysics of conventionality: the no non-causal contribution thesis (2*N*2*C*). According to 2*N*2*C*, human social practices make no non-causal contribution to the causal structure of the world, and are in that way metaphysically innocent (see Boyd 1999).

5. The Neo-Kantian Challenge: Second Version

Structural realism represents one attempt to defend scientific realism while being modest about its metaphysical implications. Putnam's "internal realism" and Fine's closely related "natural ontological attitude" (*NOA*) represent other attempts to follow scientific realists in taking the findings of science at "face value" while avoiding realism's excessively metaphysical understanding of those results (Putnam 1978, 1981, 1983a; Fine 1984, 1986a, 1986b, 1991; for a nice exposition see the Introduction to Papineau 1996; for critiques see Glymour 1982; Millikan 1986; Newton-Smith 1989a, 1989b; McMullin 1991; Papineau 1987).

"Internal realism" and *NOA* are not easy to explicate and are, almost certainly, not the same position. Nevertheless they share some important elements in common.

- "*Thin*" *Truth*: Both Putnam and Fine assert that one can (and should) accept the well established theories of science (even about unobservable) as (probably) *true*, but that this should not be understood as accepting the "metaphysical realist" (Putnam's term) view that the statements which constitute those theories *correspond to reality*. They advocate a "thin" conception of truth rather

than a correspondence conception. In Putnam's early papers defending internal realism he adopts a pragmatic conception of truth according to which truth of sentences is a matter of being epistemically acceptable in the limit of ideal inquiry. In the case of Fine, it's less clear exactly which thin conception of truth is at work.

- *De-Natured Naturalism*: Naturalistic conceptions of reference have it that reference of scientific terms is a matter of certain causal patterns which relate the use of terms to instances of their referents. Relations of measurement and detection are supposed to be centrally involved in the establishment of reference, at least in paradigm cases. It is explicit in Putnam, and surely implied by Fine's position, that *if* the causal theory of reference, and related causal theories of detection and measurement, are understood as *scientific* theories (in linguistics, say, and -- for theories of measurement and detection -- theories in the relevant sciences) then they might, for all the internal realist or *NOA*er says, be well confirmed. What is to be denied is that such conceptions underwrite a correspondence conception of truth. They are bits of science, but not (also) bits of realist naturalist philosophy.

5.1 An Analogy with Phenomenalism

An analogy with issues regarding knowledge of the external world may be helpful here. One classical early logical empiricist response to questions about our knowledge of (observable) external objects was the phenomenalist strategy of representing external objects as "logical constructions" analytically defined in sense-datum terms (see, e.g., Carnap 1928). That certain experience patterns constituted experiences of, e.g., chairs was supposed to reflect, not a discovery about some epistemically important metaphysical relation between chairs and those patterns, but, instead, the implication of the analytic definition of "chair" in the sense-datum language.

Nevertheless, nothing in the phenomenalist project was supposed to preclude the possibility that psychologists studying perception might discover that those very experience patterns are caused by light reflected off chairs and stimulating the retina is particular ways. This would be unobjectionable as a bit of empirical science, but it was not to be understood as positing an epistemically relevant relation of detection and representation between the experiential pattern and *chairs*, understood as experience-independent features of the world. It could not be understood as a component in *philosophical* justification of the claim that we know about, and "chair" refers to, experience-independent chairs.

By contrast, non-foundationalist "causal" or "reliabilist" conceptions of perceptual knowledge in the tradition initiated by Goldman (1967, 1976) would treat the relevant discovery *both* as an empirical scientific discovery *and* as a component of a (naturalistic) *philosophical* (and *epistemically relevant*) explanation of why our chair beliefs sometimes represent knowledge about (experience independent) chairs. Similarly, if the psychological findings in question were incorporated into a suitable empirical theory of language use they could, on a causal or naturalistic conception of reference, underwrite the *philosophical* conception that "chair" refers to (experience independent) chairs.

5.2 Non-Foundationalist Epistemology Again

What this suggests is that a defense of realism against internal realism or NOA must follow the lead of non-foundational causal theories of knowledge, and of perception in particular, in insisting that scientific findings about, e.g., the measurement and detection of theoretical entities, and about the reference of scientific terms have philosophical as well as scientific relevance (see, e.g., Boyd 1999, Byerly and Lazara 1973,Hacking 1982, Psillos 1999).

5.3 Challenges Regarding the Epistemology and Metaphysics of Reference and Kinds

The arguments Putnam offers in defense of internal realism are complex, and (as the critiques cited indicate) both controversial and sometimes hard to explicate. Nevertheless, it seems pretty clear that Putnam attributes to "metaphysical realism" something like the following commitments:

1. Reference is a relation between linguistic entities and entirely *extra-linguistic* (and in that sense *independently existing*) natural kinds. Natural kinds (magnitudes, etc.) are, somehow or other, out in the world, and available for discovery and naming. There is a single set of such natural entities somehow given by the structure of the world itself, independently of human practice.
2. The reference relation between natural kind (magnitude, etc.) terms and their referents is a *purely* causal matter, where the purity in question is a matter of the reference relation's being definable without significantly acknowledging descriptive elements or human intentions.

If one accepts this picture of scientific realism, understood metaphysically, then it is natural to think that what makes the associated conception of truth a *correspondence* conception is that reference is seen as a relation between terms and such *independently existing* kinds. The realist correspondence conception, so conceived, is subject to two important challenges.

First, if we think of natural kinds as things somehow independent of linguistic and methodological practices, then there are lots of natural kinds out there, and it is difficult to see how the causal conception of reference fixing could explain how a natural kind term could ever have a unique referent. This problem is exacerbated if one thinks of reference as being purely causal in the way just indicated, since intentional and descriptive factors, which might otherwise be thought to reduce the ambiguity of the reference relation, are set aside. Such considerations seem to be the basis of the "model theoretic" arguments in Putnam 1978, 1980) against "metaphysical realism."

Secondly, reference to natural kinds is supposed to explain the inductive successes of scientific practice, so there must be some quite intimate connection between natural kinds and the conceptual machinery of the sciences. If one thinks of realist theories as entailing that natural kinds are independent of that machinery, it is hard to see how the explanation could work unless it rested on something like a *objective idealist* theory according to which natural kinds are somehow metaphysically "fitted" for explanation and induction independently of the relevant practices. Such an assumption is profoundly at odds with the philosophical naturalism and metaphysical materialism ordinarily associated with scientific realism. This

sort of consideration appears to underwrite aspects of Putnam's criticism of materialist metaphysical realism in "Why There Isn't a Ready Made World" (Putnam 1983a).

5.4 Realist responses

Of these two challenges, the first has received much more attention from scientific realists. There has been widespread acceptance of the view that descriptive and/or intentional factors must figure in any scientific realist account of reference (e.g., Boyd 1999, Enç 1976, Kitcher 1992, Papineau 1979, Psillos 1999).

Much less has been said by realists about the sense, if any, in which scientific realism is committed to there being natural kinds (etc.) which are independent of us. Psillos (1999), for example, discusses problems with pure causal theories of reference extensively, but takes it to be a basic posit of scientific realism that "…the world has a definite and mind-independent natural-kind structure" (xix). Boyd (1999) offers an alternative approach according to which, like natural kind *terms* and classificatory *practices*, natural kinds themselves should be thought of as social *artifacts* deployed in achieving an appropriate fit or accommodation between inductive and explanatory practices and relevant causal structures.

Whether the intrusion of descriptive and intentional notions into realist accounts of reference, or the treatment of natural kinds as social artifacts, is compatible with the main spirit of scientific realism depends on the sense(s) in which scientific realism should be understood as entailing that the phenomena scientists study are "mind independent." A possible response to this question, compatible with the proposals just mentioned, is that the relevant sense of mind independence is fully captured by the no non-causal contribution doctrine discussed earlier.

6. The "Post-modern" Challenge

Most recent work in the relatively new discipline of science studies (see, e.g, Biagioli 1999; Galison 1987; Latour and Wolgar 1979; Latour 1987; Pickering 1984, 1995; Pinch 1985; Shapin 1982, 1994; Shapin and Schaffer 1985) and a significant body of work in feminist philosophy of science or feminist aproaches to particular science (see, e.g., Alcoff and Potter 1993; Antony 1993; Antony and Witt 1993; Conkey and Spector 1984; Fuss 1989; Gero and Conkey 1991; Harding 1986, 1987, 1991; Harding and Hintikka 1983; Harding and O'Barr 1987; Hartsock 1987; Haslanger 1993; Keller 1983: Longino 1989, 1990; Tuana 1989; Wright 1996; Wylie 1991, 1993, 2000; Wylie and Okruhlik 1987) has been to some extent influenced by, or has engaged with, anti-realist "postmodern" conceptions according to which such phenomena as science, knowledge, evidence and truth are *social constructions*, in some sense or other which implies that one should reject the idea that scientific practices achieve an approximate representational fit of some sort or other between the content of scientific theories and *the world* or *reality*.

Although serious interchanges between scientific realism and these approaches have not developed to the level of exchanges between, e.g., scientific realist approaches and logical empiricist or neo-Kantian ones,

a number of philosophers of science have defended a realist approach against post modern relativism and skepticism (see, e.g., Boyd 1999; Kitcher 1993; Papineau 1998; Pettit 1998; Sismondo 1993a, 1993b, 1996). Several factors are probably important in determining the dimensions of the dispute between realists and postmodernists.

6.1 Boundary Work

Sociologists of science have identified a feature of scientific work which is especially important when new (sub)disciplines are being established. Practitioners of emerging disciplines devote considerable effort to distinguishing the approach of their new disciplines from the approaches of more fully established disciplines, often by adopting a substantially adversarial stance towards them. This phenomenon has been played out in the establishment of science studies and (to a somewhat lesser extent)feminist philosophy. In each of these cases, mainstream realist and empiricist approaches to epistemology have been special targets of such adversarial stance taking. In the case of science studies, to a very good first approximation, the "boundary work" foundations of the emerging discipline rest on a critique of epistemology and of the correspondence conception of truth. This perfectly ordinary, and non-culpable, boundary work resistance to traditional epistemology and the correspondence theory has proven to be a barrier to communication between mainstream philosophers of science and others in science studies.

6.2 Postmodern Responses to Naive Empiricist Conceptions of Objectivity

There is a prevalent conception of scientific objectivity which is historically associated with empiricist conceptions of science, even though it is sufficiently naive that probably no professional empiricist philosopher of science ever defended all of its components. According to it, the objects of scientific study are natural kinds (etc.) which are

1. independent of human practices,
2. defined by
    a. eternal,
    b. unchanging,
    c. ahistorical, and
    d. intrinsic

    necessary and sufficient membership conditions;
3. referred to in
    a. fundamental,
    b. exceptionless,
    c. eternal, and
    d. ahistorical

    laws; and
4. discovered by the deployment of

a. eternal,
b. ahistorical,
c. politically and culturally neutral, and
d. foundational

scientific methods.

To a significant extent, anti-realist postmodern conceptions of science take these components of naive empiricism to be definitive of the notion of scientific objectivity. Postmodern students of science hold -- correctly (Boyd 1999; Sismondo 1993a, 1993b, 1996; Knorr Cetina 1993) -- that nothing in actual scientific practice even remotely fits these criteria for objectivity. On this basis they often reach the anti-realist conclusion that scientific research never achieves objective knowledge. It is characteristic of defenses of realism against postmodern anti-realism that they deny, about one or more of the components mention, that they are necessary for objective knowledge.

6.3 "Quantum Superposition" of Conceptions of Social Construction

There are, in the literature and in intellectual discourse, roughly three versions of "social constructivism," the view that science is the "social construction of reality."

1. *Neo-Kantian social constructivism*. This is the view discussed earlier according to which the adoption of a scientific paradigm *successfully* imposes a quasi-metaphysical causal structure on the phenomena scientists study.
2. *Science-as-social-process social constructivism*. This is the view that the production of scientific findings is a social process subject to the same sorts of influences -- cultural, economic, political, sociological, etc. -- which affect any other social process.
3. *Debunking social constructivism*. This is the skeptical position according to which the findings of work in the sciences are determined exclusively, or in large measure, not by the "facts," but instead by relations of social power within the scientific community and the broader community within which research is conducted.

These are quite distinct positions. For example, 1. and 3. are mutually inconsistent, and 2. is compatible with either 1., or 3., or with standard logical empiricist and scientific realist conceptions. Nevertheless, in science studies and in other disciplines influenced by postmodernism they tend to become conflated.

In the first place, many practitioners in such disciples, for reasons rehearsed above, take 2. to imply that traditional realist and empiricist conceptions are mistaken. Moreover, having adopted 2., they tend to adopt a position which looks like a quantum superposition of 1. and 3., oscillating between thinking of scientific practice as (really) constructing the (quasi-metaphysical) truth and denying that it leads to truth in any metaphysically interesting sense.

The inconsistencies involved are made clearest in cases in which scientific theories of race and gender are said to be "social constructions." Often the intent here is to engage in scientific and political criticism but,

in so far as the neo-Kantian, and the fully debunking conceptions of social construction are simultaneously operative, authors often have a difficult time finding the resources for saying that such theories are really (*really*!) false. [For discussions of these conflations and their impact on methodological and political criticism see Sismondo 1993a, 1993b, 1996; Knorr Cetina 1993; Boyd 1999.]

6.4 Naturalism and the symmetry thesis

In one of the founding documents of contemporary science studies, Barnes and Bloor (1982) criticize a tendency in the history, philosophy, and sociology of science to treat true and false scientific theories asymmetrically: explaining the acceptance of true theories as the ordinary and to-be-expected result of applying the scientific method, but explaining the acceptance of false theories by appealing instead to the operation of "social factors." They propose that explanations for the acceptance of scientific theories should be symmetrical, appealing to the same sorts of factors in explaining the acceptance of true and false theories.

In science studies, it has been nearly universal to accept the symmetry thesis *and* to interpret it as requiring that *truth* or *the facts* not be treated as among the factors involved in explaining the adoption of scientific theories. Almost certainly, a defense of scientific realism in the light of the symmetry thesis will require insisting that a *naturalistic* scientific realism *does*, by considering facts of all sorts potentially relevant to the explanation of the acceptance of scientific theories, satisfy the requirements of the symmetry thesis. The *locus classicus* for this approach is Antony 1993; it is developed in Sismondo 1999.

6.5 Essentialism

One of the most important sources of resistance to scientific realism among feminist philosophers has been the conception that realism underwrites essentialism and that essentialism is a central component of racist and sexist ideology (see Fuss 1989 for a discussion). A naturalistic version of scientific realism *does* entail a sort of essentialism about natural kinds (etc.) but that sort of essentialism need not have the form suggested by the stereotype of scientific objectivity discussed above, and need not be inimical to critiques of scientific racism or sexism (Boyd 1999, Sismondo 1996). In particular, it is compatible with the sort of realist naturalism discussed here that social categories like race and gender might have *as their essences* a certain role in the stabilization or justification of particular sorts of historically situated oppression and exploitation. Similarly, realist naturalism is compatible with the view that some social categories (like races and genders) or psychological categories (like mental illnesses) are real, but are in some respects artifacts of classificatory (and other) social practices (see, e.g., Hacking 1986a, 1986b). All that is required by naturalistic realism is that the contribution of social practices not violate 2*N*2*C*.

6.6 Concluding Remark

Scientific realism is, by the lights of most of its defenders, the sciences' own philosophy of science. Considerations of the significant philosophical challenges which it faces indicate that it can be effectively defended only by the adoption of a *meta*philosophical approach which is also closely tied to the science,

viz., some version or other of philosophical naturalism.

Social Dimensions of Scientific Knowledge

Study of the social dimensions of scientific knowledge encompasses the effects of scientific research on human life and social relations, the effects of social relations and values on scientific research, and the social aspects of inquiry itself. Several factors have combined to make these questions salient to contemporary philosophy of science. These factors include the emergence of social movements, like environmentalism and feminism, critical of mainstream science; concerns about the social effects of science-based technologies; epistemological questions made salient by big science; new trends in the history of science, especially the move away from internalist historiography; anti-normative approaches in the sociology of science; turns in philosophy to naturalism and pragmatism. This entry reviews the historical background to current research in this area, features of contemporary science which invite philosophical attention, the challenge to normative philosophy from social, cultural, and feminist studies of science, and the principal philosophical models of the social character of scientific knowledge.

---

1. Historical Background

Philosophers who study the social character of scientific knowledge can trace their lineage at least as far as John Stuart Mill. Mill, Charles Sanders Peirce, and Karl Popper all took some type of critical interaction as central to the validation of knowledge claims.

Mill's arguments occur in his well-known political essay On Liberty, (Mill 1859) rather than in the

context of his logical and methodological writings, but he makes it clear that they are to apply to any kind of knowledge or truth claim. Mill argues from the fallibility of human knowers to the necessity of unobstructed opportunity for and practice of the critical discussion of ideas. Only such critical discussion can assure us of the justifiability of the (true) beliefs we do have and can help us avoid falsity or the partiality of belief or opinion framed in the context of just one point of view. The achievement of knowledge, then, is a social or collective, not an individual, matter.

Peirce's contribution to the social epistemology of science is commonly taken to be his consensual theory of truth: "The opinion which is fated to be ultimately agreed to by all who investigate is what we mean by truth, and the object represented is the real." (Peirce 1878, 133) While often read as meaning that the truth is whatever the community of inquirers converges on in the long run, the notion in turn is interpretable as meaning more precisely either that truth (and "the real") depends on the agreement of the community of inquirers or that it is the effect of the real that it will in the end produce agreement among inquirers. Whatever the correct reading of this particular statement, Peirce elsewhere makes it clear that, in his view, truth is both attainable and beyond the reach of any individual. "We individually cannot hope to attain the ultimate philosophy which we pursue; we can only seek it for the community of philosophers." (Peirce 1868, 40). Peirce puts great stock in instigating doubt and critical interaction as means to knowledge. Thus, whether his theory of truth is consensual or realist, his view of the practices by which we attain it grants a central place to dialogue and social interaction.

Popper is often treated as a precursor of social epistemology because of his emphasis on the importance of criticism in the development of scientific knowledge. Two concepts of criticism are found in his works (Popper 1963, 1972) and these can be related to logical and practical senses of falsification. The logical sense of falsification is just the structure of a modus tollens argument, in which a hypothesis is falsified by the demonstration that one of its logical consequences is false. This is one notion of criticism, but it is a matter of formal relations between statements. The practical sense of falsification refers to the efforts of scientists to demonstrate the inadequacies of one another's theories by demonstrating observational shortcomings or conceptual inconsistencies. This is a social activity. For Popper the methodology of science is falsificationist, and science progresses through the demonstration by falsification of the untenability of theories and hypotheses. Popper's falsificationism is part of an effort to demarcate genuine science from pseudo science, and has lost its plausibility as a description of scientific methodology as the demarcation project has come under challenge from naturalist and historicist approaches in philosophy of science. While criticism does play an important role in some current approaches in social epistemology, Popper's own views are more closely approximated by evolutionary epistemology, especially that version that treats cognitive progress as the effect of selection against incorrect theories and hypotheses.

The work of Mill, Peirce, and Popper is a resource for philosophers presently exploring the social dimensions of scientific knowledge. However, the current debates are framed in the context of developments in both philosophy of science and in history and social studies of science following the collapse of the logical empiricist consensus. The philosophers of the Vienna Circle are conventionally associated with an uncritical form of positivism and with the logical empiricism that replaced American pragmatism in the 1940s and 1950s. They saw natural science, however, as a potent force for progressive

social change. (Cartwright, Cat, and Chang 1996; Giere and Richardson, eds., 1996) With its grounding in observation and public forms of verification, science for them constituted a superior alternative to what they saw as metaphysical obscurantism, an obscurantism that led not only to bad thinking but to bad politics. While one development of this point of view leads to scientism, the view that any meaningful question can be answered by the methods of science; another development leads to inquiry into what social conditions promote the growth of scientific knowledge. Logical empiricism, the version of Vienna Circle philosophy that developed in the United States, focused on logical, internal aspects of scientific knowledge and discouraged philosophical inquiry into the social dimensions of science. These came into prominence again after the publication of Thomas Kuhn's *Structure of Scientific Revolutions* (Kuhn 1962). A new generation of sociologists of science took Kuhn's emphasis on the role of non-evidential community factors in scientific change even further than he had and argued that scientific judgment was determined by social factors, such as professional interests and political ideologies. This family of positions has provoked a counter-response among philosophers. These responses are marked by an effort to grant some social character to scientific knowledge while at the same time maintaining its epistemological legitimacy, which they take to be undermined by the new sociology. At the same time, features of the organization of scientific inquiry compel philosophers to consider their implications for the normative analysis of scientific practices.

2. Big Science, Trust, and Authority

The second half of the twentieth century saw the emergence of what has come to be known as Big Science: the organization of large numbers of scientists bringing different bodies of expertise to a common research project. The original model was the Manhattan Project, undertaken during the Second World War to develop an atomic weapon. Theoretical and experimental physicists located at various sites across the country, though principally at Los Alamos, New Mexico, worked on sub-problems of the project under the overall direction of J. Robert Oppenheimer. While academic and military research have since been to some degree separated, much experimental research in physics, especially high energy particle physics, continues to be pursued by large teams of researchers. Research in other areas of science as well, for example the work comprehended under the umbrella of the Human Genome Project, has taken on some of the properties of Big Science, requiring multiple forms of expertise. In addition, the dependence of research on central funding bodies prompts questions about the degree of independence of contemporary scientific knowledge from its social and economic context.

John Hardwig (1985) articulated one philosophical dilemma posed by such large teams of researchers. Each member or subgroup participating in such a project is required because each has a crucial bit of expertise not possessed by any other member or subgroup. This may be knowledge of a part of the instrumentation, the ability to perform a certain kind of calculation, the ability to make a certain kind of measurement or observation. The other members are not in a position to evaluate the results of other members' work, and hence, all must take one anothers' results on trust. The consequence is an experimental result, (for example, the measurement of a property such as the decay rate or spin of a given particle) the evidence for which is not fully understood by any single participant in the experiment. This leads Hardwig to ask two questions, one about the evidential status of testimony, and one about the

nature of the knowing subject in these cases. With respect to the latter, Hardwig says that either the group as a whole, but no single member, knows or it is possible to know vicariously. Neither of these is palatable to him. Talking about the group or the community knowing smacks of superorganisms and transcendent entities and Hardwig shrinks from that solution. Vicarious knowledge, knowing without oneself possessing the evidence for the truth of what one knows, requires, according to Hardwig, too much of a departure from our ordinary concepts of knowledge.

The first question is, as Hardwig notes, part of a more general discussion about the epistemic value of testimony. Much of what passes for common knowledge is acquired from others. We depend on experts to tell us what is wrong with our appliances, our cars, our bodies. Indeed, much of what we later come to know depends on what we previously learned as children from our parents. We acquire knowledge of the world through the institutions of education, journalism, and scientific inquiry. Philosophers disagree about the status of beliefs acquired in this way. Here is the question: If A knows that p on the basis of evidence e, B has reason to think A trustworthy and B believes p on the basis of A's testimony that p, does B know that p? Some philosophers, like Locke and Hume, argued that only what one has observed oneself could count as a good reason for belief, and that the testimony of another is, therefore, never sufficient warrant for belief. Thus, B does not know simply on the basis of A's testimony. While this result is consistent with traditional philosophical empiricism and rationalism, which emphasized the individual's sense experience or rational apprehension as foundations of knowledge, it does have the consequence that we do not know most of what we think we know.

A number of philosophers have recently offered alternative analyses focusing on one or another element in the problem. Some argue that testimony by a qualified expert is itself evidential, (Schmitt 1988), others that the expert's evidence constitutes good reason for, but is not itself evidential for the recipient of testimony (Hardwig 1985, 1988), others that what is transmitted in testimony is knowledge and not just propositional content and thus the question of the kind of reason a recipient of testimony has is not to the point (Welbourne 1981).

However this dispute is resolved, questions of trust and authority arise in a particularly pointed way in the sciences, and Hardwig's dilemma for the physics experiment is also a specific version of a more general phenomenon. A popular conception of science, fed partly by Popper's falsificationism, is that it is epistemically reliable because the results of experiments and studies are checked by independent repetition. In practice, however, only some results are so checked and many are simply accepted on trust. Thus, just as in the non-scientific world information is accepted on trust, so in science, knowledge grows by depending on the testimony of others. What are the implications of accepting this fact for our conceptions of the reliability of scientific knowledge?

David Hull, in his (1988) argues that because the overall structure of reward and punishment in the sciences is a powerful incentive not to cheat, further epistemological analysis of the sciences is unnecessary. But some celebrated recent episodes, such as the purported production of "cold fusion" were characterized by the failure of replication attempts to produce the same phenomenon. And, while the advocates of cold fusion were convinced that their experiments had produced the phenomenon, there have also been cases of outright fraud. Thus, even if the structure of reward and punishment is an

incentive not to cheat, it does not guarantee the veridicality of every research report.

The reward individual scientists seek is credit. That is, they seek recognition, to have their work cited as important and as necessary to further scientific progress. The scientific community seeks true theories or adequate models. Credit, or recognition, accrues to individuals to the extent they are perceived as having contributed to that community goal. Without strong community policing structures, there is a strong incentive to cheat, to try to obtain credit without necessarily having done the work. Communities and individuals are then faced with the question: when is it appropriate to trust and when not?

Both Alvin Goldman (Goldman and Cox 1994) and Philip Kitcher (1993) treat this as a question to be answered by means of decision theoretic models. The decision theoretic approach to problems of trust and authority treats both credit and truth as utilities. The challenge then is to devise formulas that show that actions designed to maximize credit also maximize truth. Kitcher, in particular, develops formulas intended to show that even in situations peopled by non-epistemically motivated individuals (that is, individuals motivated more by a desire for credit than by a desire for truth), the reward structure of the community can be organized in such a way as to foster scientific progress. Kitcher also applies this approach to problems in the division of cognitive labor, i.e. to the questions whether (and when) to pursue research that calls a community consensus into question or to pursue research that extends the models and theories upon which a community agrees.

Steve Fuller and Joseph Rouse are both concerned with political dimensions of cognitive authority. Rouse in his (1987) integrated analytic and continental philosophy of science and technology to develop what might be called a critical pragmatism. This perspective facilitated an analysis of the transformative impact of science on human life and social relations. Fuller (1988) partially accepts the empirical sociologists' claim that traditional normative accounts of scientific knowledge fail to get a purchase on actual scientific practices, but takes this as a challenge to relocate the normative concerns of philosophers. These should include the distribution and circulation of knowledge claims. The task of social epistemology of science is regulation of the production of knowledge by regulating the rhetorical, technological, and administrative means of its communication.

3. Social, Cultural, and Feminist Studies of Science

Kuhn's critique of logical empiricism included a strong naturalism. Scientific rationality was to be understood by studying actual episodes in the history of science, not by formal analyses developed from a priori concepts of knowledge and reason (Kuhn 1962, 1977). Sociologists and sociologically inclined historians of science took this as a mandate for the examination of the full spectrum of scientists' practices without any prior prejudice as to which were epistemically legitimate and which not. That very distinction came under suspicion from the new social scholars, often labeled "social constructivists." They urged that understanding the production of scientific knowledge required looking at all the factors causally relevant to the acceptance of a scientific idea, not just at those the researcher thinks should be relevant.

A wide range of approaches in social and cultural studies of science has come under the umbrella label of "social constructivism." Both terms in the label are understood differently in different programs of research. While constructivists agree in holding that those factors treated as evidential, or as rationally justifying acceptance, should not be privileged at the expense of other causally relevant factors, they differ in their view of which factors are causal or worth examination. Macro-analytic approaches, such as those associated with the so-called Strong Programme in the Sociology of Scientific Knowledge, treat social relations as an external, independent variable and scientific judgment and content as a dependent variable. Micro-analyses or laboratory studies, on the other hand, abjure the implied separation of social context and scientific practice and focus on the social relations within scientific research programs and communities and on those that bind research-productive and research-receptive communities together.

Researchers also differ in the degree to which they treat the social and the cognitive dimensions of inquiry as independent or interactive. The researchers associated with the macro-analytic Strong Programme in the Sociology of Scientific Knowledge (Barry Barnes, David Bloor, Harry Collins, Donald MacKenzie, Andrew Pickering, Steve Shapin) were particularly interested in the role of large scale social phenomena, whether widely held social/political ideologies or group professional interests, on the settlement of scientific controversies. Some landmark studies in this genre include Andrew Pickering's (1984) study of competing professional interests in the interpretation of high energy particle physics experiments, and Steven Shapin and Simon Shaffer's (1985) study of the controversy between Robert Boyle and Thomas Hobbes about the proper interpretation of experiments with vacuum pumps.

The micro-sociological or laboratory studies approach features ethnographic study of particular research groups, tracing the myriad activities and interactions that eventuate in the production and acceptance of a scientific fact or datum. Karin Knorr Cetina's (1981) reports her year-long study of a plant science laboratory at UC Berkeley. Bruno Latour and Steven Woolgar's (1986) study of Roger Guillemin's neuroendocrinology laboratory at the Salk Institute is another classic in this genre. These scholars argued in subsequent work that their form of study showed that philosophical analyses of rationality, of evidence, of truth and knowledge, were irrelevant to understanding scientific knowledge. Sharon Traweek's (1988) comparative study of the cultures of Japanese and North American high energy physics communities pointed to the parallels between cosmology and social organization without making such extravagant and provocative epistemological claims. The efforts of philosophers of science to articulate norms of scientific reasoning and judgment were, to all these scholars, misdirected, because actual scientists relied on quite different kinds of considerations in the practice of science.

Until recently, apart from a few anomalous figures like Caroline Herschel, Barbara Mcclintock, and Marie Curie, the sciences were a male preserve. Feminist scholars have asked what bearing the masculinity of the scientific profession has had on the content of science and on conceptions of scientific knowledge and practice. Drawing on work by feminist scientists, exposing and critiquing gender biased science, and on theories of gender, feminist historians and philosophers of science have offered a variety of models of scientific knowledge and reasoning intended to accommodate the critique of accepted science and the concomitant proposal and advocacy of alternatives. Evelyn Keller (1985) proposed a psycho-dynamic model of knowledge and objectivity, arguing that a certain psychological profile, facilitated by typical patterns of masculine psychological development, associated knowledge and

objectivity with domination. The association of knowledge and control continues to be a topic of concern for feminist thinkers as it is also for environmentally concerned critics of the sciences. Other feminists turned to Marxist models of social relations and developed versions of standpoint theory, which holds that the beliefs held by a group reflect the social interests of that group. As a consequence, the scientific theories accepted in a context marked by divisions of power such as gender will reflect the interests of those in power. Alternative theoretical perspectives can be expected from those systematically excluded from power. (Rose 1983; Haraway 1978).

Still other feminists have argued that some standard philosophical approaches to the sciences can be used to express feminist concerns. Nelson (1990) adopts Quine's holism and naturalism to analyze debates in recent biology. Elizabeth Potter (2001) adapts Mary Hesse's network theory of scientific inference to analyse gendered aspects of 17th century physics. Helen Longino (1990) develops a contextual empiricism to analyze research in human evolution and in neuroendocrinology. In addition to the direct role played by gender bias, scholars have attended to the ways shared values in the context of reception can confer an a priori implausibility on certain ideas. Keller (1983) argued that this was the fate of Barbara McClintock's unorthodox proposals of genetic transposition. Stephen Kellert (1993) makes a similar suggestion regarding the resistance to so-called chaos theory.

What the feminist and empirical sociological analyses have in common is the view that the social organization of the scientific community has a bearing on the knowledge produced by that community. There are deep differences, however, in their views as to what features of that social organization are deemed relevant and how they are expressed in the theories and models accepted by a given community. The gender relations focused on by feminists went unrecognized by sociologists pursuing macro- or microsociological research programs. The feminist scientists and scholars further differ from the scholars in empirical social and cultural studies of science in their call for alternative theories and approaches in the sciences. These calls imply that philosophical concerns with truth and justification are not only legitimate but useful tools in advancing feminist transformative goals for the sciences. As can be seen in their varying treatments of objectivity, however, philosophical concepts are often reworked in order to be made applicable to the content or episodes of interest (Cf. Haraway 1988, Harding 1993, Keller 1985, Longino 1990, Nelson 1990)

4. Models of the Social Character of Knowledge

Since 1980, interest in developing philosophical accounts of scientific knowledge that incorporate the social dimensions of scientific practice has been on the increase. Some philosophers see attention to the social as a straightforward extension of already developed approaches in epistemology. Others, inclined toward some form of naturalism, have taken the work in empirical social studies of science discussed above seriously. They have, however, diverged quite considerably in their treatment of the social. Some, understand the social as biasing or distorting, and hence see the social as opposed to or competing with the cognitive or epistemic. They see the sociologists' disdain for normative philosophical concerns as part of a general debunking of science that demands a response. They attempt either to rebut the claims of the sociologists or to reconcile the demonstration of the role of interests in science with its ultimate

rationality. Others treat the social as instead constitutive of rationality. This division parallels to some degree the division between macro-analyses and micro-analyses in the sociology of science described above.

Philosophers who treat the social as biasing or distorting tend to focus on the constructivists' view that there are no universal principles of rationality or principles of evidence that can be used to identify in any context-independent way which factors are evidential and which not. They can be divided into roughly two camps: defenders of rationality and reconciliationists who seek to disarm the sociologists' analyses by incorporating them into a broader rational framework.

Philosophers concerned to defend the rationality of science against sociological misrepresentations include Larry Laudan (1984) James Brown (1989, 1994), Alvin Goldman (1987, 1995) and Susan Haack (1996). The details of these philosophers' approaches differ, but they agree in holding that scientists are persuaded by what they regard as the best evidence or argument, the evidence most indicative of the truth by their lights, and in holding that arguments and evidence are the appropriate focus of attention for understanding the production of scientific knowledge. When evidential considerations have not trumped non-evidential considerations, we have an instance of bad science. They read the sociologists as arguing that a principled distinction between evidential and nonevidential considerations cannot be drawn and devote their efforts to refuting those arguments. The social character of science is understood as a matter of the aggregation of individuals, not their interactions, and public knowledge as simply the additive outcome of many individuals making sound epistemic judgments. Individual rationality and individual knowledge are thus the proper focus of philosophers of science. Exhibiting principles of rationality applicable to individual reasoning is sufficient to demonstrate the rationality of science, at least in its ideal form.

Reconciliationists include Ronald Giere, Mary Hesse, and Philip Kitcher. Giere (1988) models scientific judgment using decision theory. This permits incorporating scientists' interests as one of the parameters of the decision matrix. Mary Hesse (1980) employs a network model of scientific inference that resembles W.V.O. Quine's web of belief in that its constituents are heterogeneous in character, but all subject to revision in relation to changes elsewhere in the network. She understands the social factors as coherence conditions operating in tandem with logical constraints to determine the relative plausibility of beliefs in the network.

The most elaborate reconciliationist position is that developed in Philip Kitcher's (1993). In addition to modeling relations of authority and the division of cognitive labor as described above, he offers what he terms a compromise between extreme rationalists and sociological debunkers. The compromise model appeals to a principle of rationality, which Kitcher calls the External Standard. It is deemed external because it is proposed as holding independently of any particular historical, cultural or social context. Thus, not only is it is external, but it is also universal. The principle applies to change of belief (or shift from one practice to another, in Kitcher's broader locution), not to belief. It treats a shift (in practice or belief) as rational if and only "the process through which the shift was made has a success ratio at least as high as that of any other process used by human beings (ever) ..." (Kitcher 1993, 303). Kitcher's compromise proposes that scientific ideas develop over time and benefit from the contributions of many

differently motivated researchers. This is the concession to the sociologically oriented scholars. In the end, however, those theories that get accepted are those that satisfy Kitcher's External Standard. Kitcher thus joins Goldman, Haack, and Laudan in the view that it is possible to articulate a priori conditions of rationality or of epistemic warrant that operate independently of, or, perhaps one might say, orthogonally to, the social relations of science.

A third set of models is integrationist in character. Nelson (1990) uses Quine's arguments against the independently foundational status of observation statements as the basis for what she calls a feminist empiricism. According to Nelson, no principled distinction can be made between the theories, observations, or values of a community. What counts as evidence, in her view, is fixed by the entire complex of a community's theories, value commitments, and observations. There is neither knowledge nor evidence apart from such a shared complex. The community is the primary knower on this view and individual knowledge is dependent on the knowledge and values of the community.

Miriam Solomon's social empiricism is focused on scientific rationality (Solomon 1992, 1994a, 1994b). It, too, involves denying a universal principled distinction among the causes of belief. Solomon draws on contemporary cognitive science literature to argue that biases are simply any factors that influence belief. They are not necessarily distorting, and can be productive of insight and rational belief. Salience and availability (of data, of measurement technologies) are biases as much as social ideologies. The distinctive feature of Solomon's social empiricism is her contrast between individual and community rationality. The theory or belief that it is rational to accept is that which has the greatest amount of empirical success. Individuals can persist in beliefs that are less rational than others on this view, if the totality of available evidence (or empirical data) is not available to them. What matters to science, however, is that community judgments be rational. A community is rational when the theories it accepts are those with all or the most empirical successes. Thus, the community can be rational even when its members are irrational. Indeed, individual irrationality can contribute to community rationality in that individuals committed to a theory that accounts for their data keep that data in the range of phenomena any theory accepted by the entire community must eventually explain. In order that the totality of relevant constraints on theory acceptance remain available to the entire community, biases must be appropriately distributed. Thus Solomon proposes appropriate distribution of biases as a normative condition on the structure of scientific communities.

Finally, in Longino's critical contextual empiricism, the cognitive processes that eventuate in scientific knowledge are themselves social (Longino 1990). Longino's starting point is a version of the underdetermination argument: the semantic gap between statements describing data and statements expressing hypotheses or theories to be confirmed or disconfirmed by that data means that evidential relations cannot be formally specified and that data cannot support one theory or hypothesis to the exclusion of all alternatives. Instead, such relations are mediated by background assumptions. Eventually, in the chain of justification, one reaches assumptions for which no evidence is available. If these are the context in which evidential relations are constituted, questions arise concerning how the acceptance of such assumptions can be legitimated. According to Longino, the only check against the arbitrary dominance of subjective (metaphysical, political, aesthetic) preference in such cases is critical interaction among the members of the scientific community or among members of different

communities. Longino takes the underdetermination argument to express in logical terms the point made by the sociologically oriented researchers: the individuals participating in the production of scientific knowledge are historically, geographically, and socially situated and their observations and reasoning reflect their situations. This fact does not undermine the normative enterprise of philosophy, but requires its expansion to include within its scope the social interactions within and between scientific communities. What counts as knowledge is determined by such interactions. Longino claims that scientific communities do institutionalize some critical practices (for example, peer review), but argues that such practices and institutions must satisfy conditions of effectiveness in order to qualify as objective.

5. Conclusion

Philosophical study of the social dimensions of scientific knowledge has been intensifying in the decades since 1970. Scholars continue to investigate the myriad social relations within scientific communities and between them and their social, economic, and institutional contexts. Philosophers have been focused on what might be termed narrowly epistemic concerns in their response to this work. As these stabilize, we can expect that this branch of philosophy of science will expand to include attention to the ethical and political questions its analyses make salient.

Evolutionary Epistemology

Evolutionary Epistemology is a naturalistic approach to epistemology, which emphasizes the importance of natural selection in two primary roles. In the first role, selection is the generator and maintainer of the reliability of our senses and cognitive mechanisms, as well as the "fit" between those mechanisms and the world. In the second role, trial and error learning and the evolution of scientific theories are construed as selection processes.

1. History, Problems, and Issues

Traditional epistemology has its roots in Plato and the ancient skeptics. One strand emerges from Plato's interest in the problem of distinguishing between knowledge and true belief. His solution was to suggest that knowledge differs from true belief in being justified. Ancient skeptics complained that all attempts to provide any such justification were hopelessly flawed. Another strand emerges from the attempt to provide a reconstruction of human knowledge showing how the pieces of human knowledge fit together in a structure of mutual support. This project got its modern stamp from Descartes and comes in empiricist as well as rationalist versions which in turn can be given either a foundational or coherentist

twist. The two strands are woven together by a common theme. The bonds that hold the reconstruction of human knowledge together are the justificational and evidential relations which enable us to distinguish knowledge from true belief.

The traditional approach is predicated on the assumption that epistemological questions have to be answered in ways which do not presuppose any particular knowledge. The argument is that any such appeal would obviously be question begging. Such approaches may be appropriately labeled "transcendental."

The Darwinian revolution of the nineteenth century suggested an alternative approach first explored by Dewey and the pragmatists. Human beings, as the products of evolutionary development, are natural beings. Their capacities for knowledge and belief are also the products of a natural evolutionary development. As such, there is some reason to suspect that knowing, as a natural activity, could and should be treated and analyzed along lines compatible with its status, i. e., by the methods of natural science. On this view, there is no sharp division of labor between science and epistemology. In particular, the results of particular sciences such as evolutionary biology and psychology are not ruled *a priori* irrelevant to the solution of epistemological problems. Such approaches, in general, are called naturalistic epistemologies, whether they are directly motivated by evolutionary considerations or not. Those which are directly motivated by evolutionary considerations and which argue that the growth of knowledge follows the pattern of evolution in biology are called "evolutionary epistemologies."

Evolutionary epistemology is the attempt to address questions in the theory of knowledge from an evolutionary point of view. Evolutionary epistemology involves, in part, deploying models and metaphors drawn from evolutionary biology in the attempt to characterize and resolve issues arising in epistemology and conceptual change. As disciplines co-evolve, models are traded back and forth. Thus, evolutionary epistemology also involves attempts to understand how biological evolution proceeds by interpreting it through models drawn from our understanding of conceptual change and the development of theories. The term "evolutionary epistemology" was coined by Donald Campbell (1974).

1.1 The Evolution of Epistemological Mechanisms (EEM) versus The Evolutionary Epistemology of Theories (EET)

There are two interrelated but distinct programs which go by the name "evolutionary epistemology." One focuses on the development of cognitive mechanisms in animals and humans. This involves a straightforward extension of the biological theory of evolution to those aspects or traits of animals which are the biological substrates of cognitive activity, e. g., their brains, sensory systems, motor systems, etc. The other program attempts to account for the evolution of ideas, scientific theories, epistemic norms and culture in general by using models and metaphors drawn from evolutionary biology. Both programs have their roots in 19th century biology and social philosophy, in the work of Darwin, Spencer, James and others. There have been a number of attempts in the intervening years to develop the programs in detail (see Campbell 1974, Bradie 1986, Cziko 1995). Much of the contemporary work in evolutionary epistemology derives from the work of Konrad Lorenz (1977), Donald Campbell (1974, et. al.), Karl

Popper (1972, 1984) and Stephen Toulmin (1967, 1972).

The two programs have been labeled EEM and EET. (Bradie, 1986) EEM is the label for the program which attempts to provide an evolutionary account of the development of cognitive structures. EET is the label for the program which attempts to analyze the development of human knowledge and epistemological norms by appealing to relevant biological considerations. Some of these attempts involve analyzing the growth of human knowledge in terms of selectionist models and metaphors (e. g., Popper 1972, Toulmin 1972, Hull 1988). Others argue for a biological grounding of epistemological norms and methodologies but eschew *selectionist* models of the growth of human knowledge as such (e. g., Ruse 1986, Rescher 1990).

The EEM and EET programs are interconnected but distinct. A successful EEM selectionist explanation of the development of cognitive brain structures provides no warrant, in itself, for extrapolating such models to understand the development of human knowledge systems. Similarly, endorsing an EET selectionist account of how human knowledge systems grow does not, in itself, warrant concluding that specific or general brain structures involved in cognition are the result of natural selection for enhanced cognitive capacities. The two programs, though similar in design and drawing upon the same models and metaphors, do not stand or fall together.

1.2 Ontogeny versus Phylogeny

Biological development involves both ontogenetic and phylogenetic considerations. Thus, the development of specific traits, such as the opposable thumb in humans, can be viewed both from the point of view of the development of that trait in individual organisms (ontogeny) and the development of that trait in the human lineage (phylogeny). The development of knowledge and knowing mechanisms exhibits a parallel distinction. We can consider the growth of an individual’s corpus of knowledge and epistemological norms or his or her brain (ontogeny) or the growth of human knowledge and establishment of epistemological norms across generations or the development of brains in the human lineage (phylogeny). The EEM/EET distinction cuts across this distinction since we may be concerned either with the ontogenetic or phylogenetic development of, e. g., the brain or the ontogenetic or phylogenetic development of norms and knowledge corpora. One might expect that since current orthodoxy maintains that biological processes of ontogenesis proceed differently from the selectionist processes of phylogenesis, evolutionary epistemologies would reflect this difference. Curiously enough, however, for the most part they do not. For example, the theory of "neural Darwinism" as put forth by Edelman (1987) and Changeaux (1985) offers a selectionist account of the ontogenetic development of the neural structures of the brain. Karl Popper’s conjectures and refutations model of the development of human knowledge is a well known example of a selectionist account which has been applied both to the ontogenetic growth of knowledge in individuals as well as the trans-generational (phylogenetic) evolution of scientific knowledge. B. F. Skinner’s theory of operant conditioning, which deals with the ontogenesis of individual behavior, is explicitly based upon the Darwinian selectionist model. (Skinner 1981)

1.3 Descriptive versus Prescriptive Approaches

A third distinction concerns descriptive versus prescriptive approaches to epistemology and the growth of human knowledge. Traditionally, epistemology has been construed as a normative project whose aim is to clarify and defend conceptions of knowledge, foundations, evidential warrant and justification. Many have argued that neither the EEM programs nor the EET programs have anything at all to do with epistemology properly (i. e., traditionally) understood. The basis for this contention is that epistemology, properly understood, is a normative discipline, whereas the EEM and EET programs are concerned with the construction of causal and genetic (i.e., descriptive) models of the evolution of cognitive capacities or knowledge systems. No such models, it is alleged, can have anything important to contribute to normative epistemology (e.g., Kim 1988). The force of this complaint depends upon how one construes the relationship between evolutionary epistemology and the tradition.

There are three possible configurations of the relationship between descriptive and traditional epistemologies. (1) Descriptive epistemologies can be construed as competitors to traditional normative epistemologies. On this view, both are trying to address the same concerns and offering competing solutions. Riedl (1984) defends this position. A standard objection to such approaches is that descriptive accounts are not adequate to do justice to the prescriptive elements of normative methodologies. The extent to which an evolutionary approach contributes to the resolution of traditional epistemological and philosophical problems is a function of which approach one adopts (cf. Dretske 1971, Bradie 1986, Ruse 1986, Radnitsky and Bartley 1987, Kim 1988). (2) Descriptive epistemology might be seen as a successor discipline to traditional epistemology. On this reading, descriptive epistemology does not address the questions of traditional epistemology because it deems them irrelevant or unanswerable or uninteresting. Many defenders of naturalized epistemologies fall into this camp (e.g., Munz 1993). (3) Descriptive epistemology might be seen as complementary to traditional epistemology. This appears to be Campbell's view. On this analysis, the function of the evolutionary approach is to provide a descriptive account of knowing mechanisms while leaving the prescriptive aspects of epistemology to more traditional approaches. At best, the evolutionary analyses serve to rule out normative approaches which are either implausible or inconsistent with an evolutionary origin of human understanding.

1.4 Future Prospects

EEM programs are saddled with the typical uncertainties of phylogenetic reconstructions. Is this or that organ or structure an adaptation and if so, for what? In addition, there are the uncertainties which result from the necessarily sparse fossil record of brain and sensory organ development. The EET programs are even more problematic. While it is plausible enough to think that the evolutionary imprint on our organs of thought influences what and how we do think, it is not at all clear that the influence is direct, significant or detectible. Selectionist epistemologies which endorse a "trial and error" methodology as an appropriate model for understanding scientific change are not analytic consequences of accepting that the brain and other ancillary organs are adaptations which have evolved primarily under the influence of natural selection. The viability of such selectionist models is an empirical question which rests on the development of adequate models. Hull's (1988) is, as he himself admits, but the first step in that

direction. Cziko (1995) is a manifesto urging the development of such models (cf. also the evolutionary game theory modeling approach of Harms 1997). Much hard empirical work needs to be done to sustain this line of research. Non-selectionist evolutionary epistemologies, along the lines of Ruse (1986), face a different range of difficulties. It remains to be shown that any biological considerations are sufficiently restrictive to narrow down the range of potential methodologies in any meaningful way.

Nevertheless, the emergence in the latter quarter of the twentieth century of serious efforts to provide an evolutionary account of human understanding has potentially radical consequences. The application of selectionist models to the development of human knowledge, for example, creates an immediate tension. Standard traditional accounts of the emergence and growth of scientific knowledge see science as a progressive enterprise which, under the appropriate conditions of rational and free inquiry, generates a body of knowledge which progressively converges on the truth. Selectionist models of biological evolution, on the other hand, are generally construed to be non-progressive or, at most, locally so. Rather than generating convergence, biological evolution produces diversity. Popper's evolutionary epistemology attempts to embrace both but does so uneasily. Kuhn's "scientific revolutions" account draws tentatively upon a Darwinian model, but when criticized, Kuhn retreated. (cf Kuhn 1972, pp 172f with Lakatos and Musgrave 1970, p. 264) Toulmin (1972) is a noteworthy exception. On his account, concepts of rationality are purely "local" and are themselves subject to evolution. This, in turn, seems to entail the need to abandon any sense of "goal directedness" in scientific inquiry. This is a radical consequence which few have embraced. Pursuing an evolutionary approach to epistemology raises fundamental questions about the concepts of knowledge, truth, realism, justification and rationality.

The interested reader should consult the extensive bibliography originally developed by Donald Campbell and maintained by Gary Cziko at <http://faculty.ed.uiuc.edu/g-cziko/stb/>.

2. Formal Models

Every scientific enterprise requires formal and semi-formal models which allow the quantitative characterization of its objects of study. The attempt to transform the philosophical study of knowledge into a scientific discipline which approaches knowledge as a biological phenomenon is no different. Much of the evolutionary epistemology literature has been concerned with how to conceive of knowledge as a natural phenomenon, what difference this would make to our understanding of our place in the world, and with answering objections to the project. There are, as well, a number of more technical projects which attempt to provide the theoretical tools necessary for a naturalistic epistemology.

2.1 Static Optimization Models

In the simplest sort of model, an organism has to deal with an environment that has two states, S_1 and S_2, and has two possible responses R_1 and R_2. We suppose that what the organism does in each state makes a difference to its fitness. Fitnesses are usually written characterized by a matrix W.

The individual elements of the matrix W_{ij} are the fitness consequences of response *i* in state *j*. So, for instance, W_{21} denotes the fitness consequences of R_2 in S_1. If we let W_{11} and W_{22} equal one and W_{12} and W_{21} equal zero, then there is a clear evolutionary advantage to performing R_1 in S_1 and R_2 in S_2.

However, the organism must first detect the state of the environment, and detectors are not in general perfectly reliable. If the organism responds automatically to the detector, we can use the probabilities of responses given states to characterize the reliability of the detector. We write the probability of R_1 given S_1 as $\Pr(R_1|S_1)$. This allows us to calculate that responding to the detector rather than always choosing R_1 or R_2 will be advantageous just in case the following inequality holds (cf. Godfrey-Smith 1996):

$$\Pr(R_2|S_2) /(1 - \Pr(R_1|S_1)) > \Pr(S_1)(W_{11} - W_{21})/(1-\Pr(S_1))(W_{22} - W_{12})$$

This simple model demonstrates that whether or not flexible responses are adaptive depends on the particular characteristics of the fitness differences that the responses make, the probability of the various states of the environment, and the reliability of the detector. The particular result is calculated assuming that detecting the environmental state and the flexible response system is free in evolutionary terms. More complete analyses would include the costs of these factors.

Static optimization models like the one outlined above can be extended in several ways. Most obviously, the number of environmental states and organismic responses can be increased, but there are other modifications that are more interesting. Signal detection theory, for instance, models the detectors and cues in more detail. In one example, a species of "sea moss" detects the presence of predatory sea slugs via a chemical cue. They respond by growing spines, which is costly. The cue in this case, the water-borne chemical, comes in a variety of concentrations, which indicate various levels of danger. Signal detection theory allows us to calculate the best threshold value of the detector for the growing of spines.

Static models depict evolutionary processes in terms of fitness costs and benefits. They are static in the sense that they model no actual process, but merely calculate the direction of change for different situations. If fitness is high, a type will increase, if low it will decrease. When fitnesses are equal, population proportions remain at stable equilibrium. Dynamic models typically employ the kinds of calculations involved in static models to depict actual change over time in population proportions. Instead of calculating whether change will occur and in what direction, dynamic models follow change.

2.2 Population Dynamics

Population dynamics, sometimes referred to as "replicator dynamics", offers a tractable way to model the evolution of populations over time under the kinds of selective pressures that can be characterized by static optimization models. This is often necessary, since the dynamics of such populations are often difficult to predict purely on the basis of static considerations of payoff differences. The so-called "replicator dynamics" were named by Taylor and Jonker (1978) and generalized by Schuster and Sigmund (1983) and Hofbauer and Sigmund (1988). They trace their source back to the seminal work of

R.A. Fisher in the 1920's and 30's. The generalization covers evolutionary models used in population genetics, evolutionary game theory, ecology, and the study of prebiotic evolution. The models can be implemented either mathematically or computationally, and can model either stepwise (discrete) or continuous evolutionary change.

Population dynamics models the evolution of populations. A population is a collection of individuals, which are categorized according to type. The types in genetics are genes, in evolutionary game theory, strategies. The types of interest in epistemological models would be types of cognitive apparatuses, or cognitive strategies -- ways of responding to environmental cues, ways of manipulating representations, and so forth. Roughly, EEM models focus on the inherited and EET models focus on the learned. The evolution of the population consists in changes of the relative frequency of the different types within the population. Selection, typified by differential reproductive success, is represented as follows. Each type has a growth rate or "fitness", designated by *w*, and a frequency designated by *p*. The frequency of type *i* at the next generation p_i' is simply the old frequency multiplied by the fitness and divided by the mean fitness of the population "$\overline{w}$".

$$p_i' = p_i \cdot w_i / \overline{w}$$

Division by $\overline{w}$ has the effect of "normalizing" the frequencies, so that they add up to one after each is multiplied by its fitness. It also makes evident that the frequency of a type will increase just in case its fitness is higher than the current population average.

Fitness

Fitnesses, which should be understood simply as the aggregation of probable-growth factors that drive the dynamics of large populations, may depend on a variety of factors. Fitness components differ from variation components in that they affect population frequencies proportionally to those frequencies, that is to say, multiplicatively. Fitness component in biological evolution include mortality and reproductive rate. In cultural evolution, they include transmission probability and rejection probability. Within either sort of model, what matters is how fitnesses change as a result of other changing factors within the model. In the simplest cases, fitnesses are fixed and the type with the highest fitness inevitably dominates the population. In more complex cases, fitnesses may depend on variable factors like who one plays against, or the state of a variable environment. Most commonly, variable fitnesses are calculated using a payoff matrix like the one above. In general, to calculate the expected fitness of a type, one multiplies the fitness a type would have in each situation times the likelihood that individuals in the population will confront that situation and adds the resulting products.

$$w_i = \mathrm{S}_A \, \Pr(A) \cdot W_{iA}$$

where W_{iA} is type i's fitness in situation *A*. This sort of calculation assumes that the effects of the various situations are additive. More complex situations can be modeled, of course, but additive matrices are the standard. It should be noted, however, that matrix-driven evolution can exhibit quite complex behavior.

For instance, chaotic behavior is possible with as few as four strategies (Skyrms 1992).

Some relationships may be represented without a matrix. Boyd and Richerson (1985), for instance, were interested in a special kind of frequency dependent transmission bias in culture, where being common conferred an advantage due to imitators "doing as the Romans do." In such a case, the operative fitness of the type is just the fitness as calculated according to the usual factors, and then modified as a function of the frequency of the type.

Continuity and Computation

The conceptual bases of replicator dynamics are quite straightforward. Getting results typically requires one of two approaches. In order to prove more than rudimentary mathematical results, one typically needs to derive a continuous version of the dynamics. The basic form is

$$dp_i/dt = p(w_i - \overline{w})$$

with fitnesses calculated as usual. Mathematical approaches have been quite productive, though the bulk of theoretical results apply primarily to population genetics. See Hofbauer and Sigmund (1988) for a compendium of such results, as well as a reasonable graduate-level introduction to the mathematical study of evolutionary processes.

The second approach is computational. With the increase in power of personal computers, computational implementation of evolutionary models become increasingly attractive. They require only rudimentary programming skills, and are in general much more flexible in the assumptions they require. The general strategy is to create an array to hold population frequencies and fitnesses, and then a series of procedures (or methods or functions) which

1. calculate fitnesses,
2. update frequencies with the new fitnesses, and
3. manage interface details like outputting the new state of the population to a file or the screen.

A loop then runs the routines in sequence, over and over again. Most modelers are happy to put their source code on the internet, which is probably the best place to find it.

Modeling Cultural Evolution

Part of the difficulty in understanding cognitive behavior as the product of evolution is that there are at least three very different evolutionary processes involved. First, there is the biological evolution of cognitive and perceptual mechanisms via genetic inheritance. Second, there is the cultural evolution of languages and concepts. Third, there is the trial-and-error learning process that occurs during an individual’s lifetime. Moreover, there is some reason to agree with Donald T. Campbell that

understanding human knowledge fully will require understanding the interaction between these processes. This requires that we be able to model both processes of biological and cultural evolution. There are by now a number of well-established models of biological evolution. Cultural evolution presents more novelty.

Perhaps the most popular attempt to understand cultural evolution is Richard Dawkins' (1976) invention of the "meme." Dawkins observed that what lies at the heart of biological evolution is differential reproduction. Evolution in general was then the competitive dynamics of lineages of self-replicating entities. If culture was to evolve, on this view, there had to be cultural "replicators", or entities whose differential replication in culture constituted the cultural evolutionary process. Dawkins dubbed these entities "memes", and they were characterized as informational entities which infect our brains, "leaping from head to head" via what we ordinarily call imitation. Common examples include infectious tunes, and religious ideologies. The main difficulty with this approach has been with providing specifications for the basic entities. The identity conditions of genes can be given, in theory, in terms of sequences of base pairs in chromosomes. There appears to be no such fundamental "alphabet" for the items of cultural transmission. Consequently, the project of "memetics" as contending basis for evolutionary epistemology is on hold pending an adequate understanding of its basic ontology. [See the online Journal of Memetics for more information.]

Population models have been used to good effect in modeling cultural transmission processes. Evolutionary game theory models are frequently claimed to cover both processes in which strategies are inherited and those in which they are imitated. This application is possible in the absence of any specification of the underlying nature of strategies, for instance, whether they are to be thought of as "things" which are replicated, or whether they are properties or states of the individuals whose strategies they are. This is sometimes referred to as the "epidemiological approach", though again, the comparison to infection is due to the quantitative tools used in analysis rather than to any presupposition regarding the underlying ontology of cultural transmission.

2.3 Multi-Level Evolution

The kind of levels involved in evolutionary epistemology are quite different than the kind of levels of selection which are discussed much more often in the "levels of selection" debate in evolutionary biology. In evolutionary biology, the "levels" of selection under discussion are levels of scale. The debate concerns whether genes are always the "units" or "targets" of selection, or whether selection can occur on higher levels, like organisms, groups, and species. The levels involved in evolutionary epistemology, on the other hand, are levels of the regulatory hierarchy involved in the control of behavior. These include the genetic bases of cognitive and perceptual hardware, concepts, languages, techniques, beliefs, preferences, and so forth. Note that in the case of evolutionary epistemology, the terms "levels" and "hierarchy" may be impressionistic. There is often no clear arrangement of levels at all.

There are at least two different approaches that have been taken to modeling multi-level evolution.

1. Dual Transmission Models: Boyd and Richerson (1985) adapted models from genetics to model a case in which a trait (cooperation) was affected both by genetic and cultural evolution. It was first shown that a genetically determined bias on cultural transmission could be selected for in a migratory population. The bias made it easier to pick up local customs, increasing the likelihood of imitation beyond that determined by the frequency and perceived value of the behavior. Once this bias was in place, its effect was strong enough to overcome the perceived costs involved in cooperative behavior. The model yielded two important results. First, it provided a novel mechanism according to which cooperative behavior can stabilize in migratory populations. But more importantly, it demonstrated that cultural evolution cannot be predicted purely on the basis of genetic fitnesses.
2. Multiple Population Models: Harms (1997) constructed a multi-level dynamic population model of bumblebee learning. Mutual information between distributions of sensor types, overt foraging behaviors, and internal foraging preferences on the one hand and environmental states on the other was assessed and compared to average fitness of the population states. It was shown that information present in overt behaviors may be underutilized, and that exaptation of sensor mechanisms for preference formation can bring about the utilization of that information.

2.4 Meaning

Full descriptive accounts of truth and justification both demand a theory of meaning. Until a sign has meaning, it cannot be true or false. Moreover, determining the meaning of justificatory claims may provide a descriptive theory of justification. Presumably, what makes a claim of justification true is the basis of that justification. If meaning is conventional, then the evolution of meaning becomes an instance of the evolution of conventions.

Models of the evolution of conventions have in one case been extended to apply to meaning conventions. Skyrms (1996, chapter 5) gave an evolutionary interpretation of David Lewis' (1969) model of rational selection of meaning conventions. Skyrms was able to show that there is strong selection on the formation of "signaling systems" in mixed populations with a full set of coordinated, countercoordinated, and uncoordinated strategies. It is significant that the structure of the model and the selective process by which meaning conventions emerge and are stabilized largely parallels the account of the evolution of meaning given by Ruth Millikan (1984).

In the simplest version, the model is constructed as follows: We imagine that there are two states of affairs T, two acts A, and two signals M. Players have an equal chance of being in either the position of sender, or receiver. Receivers must decide what to do based purely on what the sender tells them. In this purely cooperative version, each player gets one point if the receiver does A_1 if the state is T_1 or A_2 if the state is T_2.

Since players will be both sender and receiver, they must have a strategy for each situation. There are sixteen such strategies, and we suppose them to be either inherited (or learned) from biological parents, or imitated on the basis of perceived success in terms of points earned. Strategies I_1 and I_2 are signaling

systems, in that if both players play the same one of these two strategies they will always get their payoff. I_3 and I_4 are anti-signaling strategies, which result in consistent miscoordination, though they do well against each other. All of the other strategies involve S_3, S_4, R_3, or R_4, which results in the same act being performed no matter what the external state is.

Sender Strategies:

S_1: Send M_1 if T_1; M_2 if T_2

S_2: Send M_2 if T_1;M_1 if T_2

S_3: Send M_1 if T_1 or T_2

S_4: Send M_2 if T_1 or T_2

Receiver Strategies:

R_1: Do A_1 if M_1; A_2 if M_2

R_2: Do A_2 if M_1; A_1 if M_2

R_3: Do A_1 for M_1 or M_2

R_4: Do A_2 for M_1 or M_2

Complete Strategies:

I_1: S_1,R_1

I_2: S_2,R_2,

I_3: S_1,R_2

I_4: S_2,R_2

I_5: S_1,R_3

I_6: S_2,R_3

I_7: S_1,R_4

I_8: S_2,R_4

I_9: S_3,R_1

I_{10}: S_3,R_2

I_{11}: S_3,R_3

I_{12}: S_3,R_4

I_{13}: S_4,R_1

I_{14}: S_4,R_2

I_{15}: S_4,R_3

I_{16}: S_4,R_4

Simulation results showed that virtually all initial population distributions become dominated by one or the other of the two signaling system strategies. The situation becomes more complex when more realistic payoffs are introduced, for instance, that the sender incurs a cost rather than automatically sharing the benefit that the receiver gets from correct behavior for the environment. Even in such situations, however, the most likely course of evolution is domination by a signaling system.

Game Theory

Game theory is the study of the ways in which *strategic interactions* among *rational players* produce *outcomes* with respect to the *preferences* (or *utilities*) of those players, none of which might have been intended by any of them. The meaning of this statement will not be clear to the non-expert until each of the italicized words and phrases has been explained and featured in some examples. Doing this will be the main business of this article. First, however, we provide some historical and philosophical context in order to motivate the reader for all of this technical work ahead.

1. Philosophical and Historical Motivation

The mathematical theory of games was invented by John von Neumann and Oskar Morgenstern (1944). For reasons to be discussed later, limitations in their mathematical framework initially made the theory applicable only under special and limited conditions. This situation has gradually changed, in ways we will examine as we go along, over the past six decades, as the framework was deepened and generalized. Refinements are still being made, and we will review a few outstanding philosophical problems that lie along the advancing front edge of these developments towards the end of the article. However, since at least the late 1970s it has been possible to say with confidence that game theory is the most important and useful tool in the analyst's kit whenever she confronts situations in which one agent's rational decision-making depends on her expectations about what one or more other agents will do, and theirs similarly depend on expectations about her.

Despite the fact that game theory has been rendered mathematically and logically systematic only recently, however, game-theoretic insights can be found among philosophers and political commentators going back to ancient times. For example, Plato, in the *Republic*, at one point has Socrates worry about the following situation. Consider a soldier at the front, waiting with his comrades to repulse an enemy attack. It may occur to him that if the defense is likely to be successful, then it isn't very probable that his own personal contribution will be essential. But if he stays, he runs the risk of being killed or wounded -- apparently for no point. On the other hand, if the enemy is going to win the battle, then his chances of death or injury are higher still, and now quite clearly to no point, since the line will be overwhelmed anyway. Based on this reasoning, it would appear that the soldier is better off running away regardless of who is going to win the battle. Of course, if all of the soldiers reason this way -- as they all apparently *should*, since they're all in identical situations -- then this will certainly *bring about* the outcome in which the battle is lost. Of course, this point, since it has occurred to us as analysts, can occur to the soldiers too. Does this give them a reason for staying at their posts? Just the contrary: the greater the soldiers' fear that the battle will be lost, the greater their incentive to get themselves out of harm's way. And the greater the soldiers' belief that the battle will be won, without the need of any particular individual's contributions, the less reason they have to stay and fight. If each soldier *anticipates* this sort of reasoning on the part of the others, all will quickly reason themselves into a panic, and their horrified commander will have a rout on his hands before the enemy has even fired a shot!

Long before game theory had come along to show people how to think about this sort of problem systematically, it had occurred to some actual military leaders and influenced their strategies. Thus the Spanish conqueror Cortez, when landing in Mexico with a small force who had good reason to fear their capacity to repel attack from the far more numerous Aztecs, removed the risk that his troops might think their way into a retreat by burning the ships on which they had landed. With retreat having thus been rendered physically impossible, the Spanish soldiers had no better course of action but to stand and fight -- and, furthermore, to fight with as much determination as they could muster. Better still, from Cortez's point of view, his action had a discouraging effect on the motivation of the Aztecs. He took care to burn his ships very visibly, so that the Aztecs would be sure to see what he had done. They then reasoned as follows: Any commander who could be so confident as to willfully destroy his own option to be prudent if the battle went badly for him must have good reasons for such extreme optimism. It cannot be wise to attack an opponent who has a good reason (whatever, exactly, it might be) for being sure that he can't lose. The Aztecs therefore retreated into the surrounding hills, and Cortez had his victory bloodlessly.

This situation, as imagined by Plato and as vividly acted upon by Cortez, has a deep and interesting logic. Notice that the soldiers are not motivated to retreat *just*, or even mainly, by their rational assessment of the dangers of battle and by their self-interest. Rather, they discover a sound reason to run away by realizing that what it makes sense for them to do depends on what it will make sense for others to do, and that all of the others can notice this too. Even a quite brave soldier may prefer to run rather than heroically, but pointlessly, die trying to stem the oncoming tide all by himself. Thus we could imagine, without contradiction, a circumstance in which an army, all of whose members are brave, flees at top speed before the enemy makes a move. If the soldiers really *are* brave, then this surely isn't the outcome any of them wanted; each would have preferred that all stand and fight. What we have here, then, is a case in which the *interaction* of many individually rational decision-making processes -- one process per soldier -- produces an outcome intended by no one. (Most armies try to avoid this problem just as Cortez did. Since they can't usually make retreat *physically* impossible, they make it *economically* impossible: they shoot deserters. Then standing and fighting is each soldier's individually rational course of action after all, because the cost of running is sure to be at least as high as the cost of staying.)

Another classic source that reproduces exactly this sequence of reasoning is Shakespeare. In *Henry V*, he has the victor of Agincourt explain his decision to slaughter French prisoners, in full view of the enemy, as follows. His own troops observe that the prisoners have been killed, and observe that the enemy has observed this. Therefore, they know what fate will await them at the enemy's hand if they don't win. Metaphorically, but very effectively, their boats have been burnt. The French prisoners died as a means by which Henry sent a signal to *his own troops*, thereby changing their incentives.

These examples might seem to be relevant only for those who find themselves in sordid situations of cut-throat competition. Perhaps, one might think, it is important for generals, politicians, businesspeople and others whose jobs involve manipulation of others, but the philosopher should only deplore its horrid morality. Such a conclusion would be highly premature, however. The study of the *logic* that governs the interrelationships amongst incentives, strategic interactions and outcomes has been fundamental in modern political philosophy, since centuries before anyone had an explicit name for this sort of logic.

Hobbes's *Leviathan* is often regarded as the founding work in modern political philosophy, the text that began the continuing round of analyses of the function and justification of the state and its restrictions on individual liberties. The core of Hobbes's reasoning can be given quite straightforwardly as follows. The best situation for all people is one in which each is free to do as she pleases. Often, such free people will wish to cooperate with one another in order to carry out projects that would be impossible for an individual acting alone. But if there are any immoral or amoral agents around, they will notice that their interests are best served by getting the benefits from cooperation and not returning them. Suppose, for example, that you agree to help me build my house in return for my promise to help you build yours. After my house is finished, I can make your labour free to me simply by reneging on my promise. I then realize, however, that if this leaves you with no house, you will have an incentive to take mine. This will put me in constant fear of you, and force me to spend valuable time and resources guarding myself against you. I can best minimize these costs by striking first and killing you at the first opportunity. Of course, you can anticipate all of this reasoning by me, and so have good reason to try to beat me to the

punch. Since I can anticipate *this* reasoning by *you*, my original fear of you was not paranoid; nor was yours of me. In fact, neither of us actually needs to be immoral to get this chain of mutual reasoning going; we need only think that there is some *possibility* that the other might try to cheat on bargains. Once a small wedge of doubt enters any one mind, the incentive induced by fear of the consequences of being *preempted* -- hit before hitting first -- quickly becomes overwhelming on both sides. If either of us has any resources of our own that the other might want, this murderous logic will take hold long before we are so silly as to imagine that we could ever actually get so far as making deals to help one another build houses in the first place. Left to their own devices, rational agents will never derive the benefits of cooperation, and will instead live from the outset in a state of 'war of all against all', in Hobbes's words. In these circumstances, all human life, as he vividly and famously put it, will be "solitary, poor, nasty, brutish and short."

Hobbes's proposed solution to this problem was tyranny. The people can hire an agent -- a government -- whose job is to punish anyone who breaks any promise. So long as the threatened punishment is sufficiently dire -- Hobbes thought decapitation generally appropriate -- then the cost of reneging on promises will exceed the cost of keeping them. The logic here is identical to that used by an army when it threatens to shoot deserters. If all people know that these incentives hold for most others, then cooperation will not only be possible, but will be the expected norm, and the war of all against all becomes a general peace.

Hobbes pushes the logic of this argument to a very strong conclusion, arguing that it implies not only a government with the right and the power to enforce cooperation, but an 'undivided' government in which the arbitrary will of a single ruler must impose absolute obligation on all. Few contemporary political theorists think that the particular steps by which Hobbes reasons his way to this conclusion are both sound and valid. Working through these issues here, however, would carry us away from our topic into complex details of contractarian political philosophy. What is important in the present context is that these details, as they are in fact pursued in the contemporary debates, all involve sophisticated interpretation of the issues using the resources of modern game theory. Furthermore, Hobbes's most basic point, that the fundamental justification for the coercive authority and practices of governments is peoples' own need to protect themselves from what game theorists call 'social dilemmas', is accepted by many, if not most, political theorists. Notice that Hobbes has *not* argued that tyranny is a desirable thing in itself. The structure of his argument is that the logic of strategic interaction leaves only two general political outcomes possible: tyranny and anarchy. Rational agents then choose tyranny as the lesser of two evils.

The reasoning of Cortez, of Henry V and of Hobbes's political agents has a common logic, one derived from their situations. In each case, the aspect of the environment that is most important to the agents' achievement of their preferred outcomes is the set of expectations and possible reactions to their strategies by other agents. The distinction between acting *parametrically* on a passive world and acting *non-parametrically* on a world that tries to act in anticipation of these actions is fundamental. If you wish to kick a rock down a hill, you need only concern yourself with the rock's mass relative to the force of your blow, the extent to which it is bonded with its supporting surface, the slope of the ground on the other side of the rock, and the expected impact of the collision on your foot. The values of all of these variables are independent of your plans and intentions, since the rock has no interests of its own and takes no actions to

attempt to assist or thwart you. By contrast, if you wish to kick a person down the hill, then unless that person is unconscious, bound or otherwise incapacitated, you will likely not succeed unless you can disguise your plans until it's too late for him to take either evasive or forestalling action. The logical issues associated with the second sort of situation are typically much more complicated, as a simple hypothetical example will illustrate.

Suppose first that you wish to cross a river that is spanned by three bridges. (Assume that swimming, wading or boating across are impossible.) The first bridge is known to be safe and free of obstacles; if you try to cross there, you will succeed. The second bridge lies beneath a cliff from which large rocks sometimes fall. The third is inhabited by deadly cobras. Now suppose you wish to rank-order the three bridges with respect to their preferability as crossing-points. Your task here is quite straightforward. The first bridge is obviously best, since it is safest. To rank-order the other two bridges, you require information about their relative levels of danger. If you can study the frequency of rock-falls and the movements of the cobras for awhile, you might be able to calculate that the cobra bridge is four times more dangerous than the rocky bridge, and the rocky bridge 20% more dangerous than the unobstructed bridge. Your reasoning here is strictly parametric because neither the rocks nor the cobras are trying to influence your actions, by, for example, concealing their typical patterns of behaviour because they know you are studying them. It is quite obvious what you should do here: cross at the safe bridge. Now let us complicate the situation a bit. Suppose that the bridge with the rocks was immediately before you, while the safe bridge was a day's difficult hike upstream. Your decision-making situation here is slightly more complicated, but it is still strictly parametric. You would have to decide whether the cost of the long hike was worth exchanging for the penalty of a 20% chance of being hit by a rock. However, this is all you must decide, and your probability of a successful crossing is entirely up to you; the environment is not interested in your plans.

However, if we now complicate the situation in the direction of non-parametricity, it becomes much more puzzling. Suppose that you are a fugitive of some sort, and waiting on the other side of the river with a gun is your pursuer. She will catch and shoot you, let us suppose, only if she waits at the bridge you try to cross; otherwise, you will escape. As you reason through your choice of bridge, it occurs to you that she is over there trying to anticipate your reasoning. It will seem that, surely, choosing the safe bridge straight away would be a mistake, since that is just where she will expect you, and your chances of death rise to certainty. So perhaps you should risk the rocks, since these odds are much better. But wait ... if you can reach this conclusion, your pursuer, who is just as rational and well-informed as you are, can anticipate that you will reach it, and will be waiting for you if you evade the rocks. So perhaps you must take your chances with the cobras; that is what she must least expect. But, then, no ... if she expects that you will expect that she will least expect this, then she will most expect it. This dilemma, you realize with dread, is general: you must do what your pursuer least expects; but whatever you most expect her to least expect is automatically what she will most expect. You appear to be trapped in indecision. All that might console you a bit here is that, on the other side of the river, your pursuer is trapped in exactly the same quandary, unable to decide which bridge to wait at because as soon as she imagines committing to one, she will notice that if she can find a best reason to pick a bridge, you can anticipate that same reason and then avoid her.

We know from experience that, in situations such as this, people do not usually stand and dither in circles forever. As we'll see later, there *is* a rational solution -- that is, a best rational action -- available to both players. However, until the 1940s neither philosophers nor economists knew how to find it mathematically. As a result, economists were forced to treat non-parametric influences as if they were complications on parametric ones. This is likely to strike the reader as odd, since, as our example of the bridge-crossing problem was meant to show, non-parametric features are often fundamental features of decision-making problems. Part of the explanation for game theory's relatively late entry into the field lies in the problems with which economists had historically been concerned. Classical economists, such as Adam Smith and David Ricardo, were mainly interested in the question of how agents in very large markets -- whole nations -- could interact so as to bring about maximum monetary wealth for themselves. Smith's basic insight, that efficiency is best maximized by agents freely seeking mutually advantageous bargains, was mathematically verified in the twentieth century. However, the demonstration of this fact applies only in conditions of ‘perfect competition,’ that is, when firms face no costs of entry or exit into markets, when there are no economies of scale, and when no agents' actions have unintended side-effects on other agents' well-being. Economists always recognized that this set of assumptions is purely an idealization for purposes of analysis, not a possible state of affairs anyone could try (or should want to try) to attain. But until the mathematics of game theory matured near the end of the 1970s, economists had to hope that the more closely a market *approximates* perfect competition, the more efficient it will be. No such hope, however, can be mathematically or logically justified in general; indeed, as a strict generalization the assumption can be shown to be false.

This article is not about the foundations of economics, but it is important for understanding the origins and scope of game theory to know that perfectly competitive markets have built into them a feature that renders them susceptible to parametric analysis. Because agents face no entry costs to markets, they will open shop in any given market until competition drives all profits to zero. This implies that if costs and demand are fixed, then agents have no options about how much to produce if they are trying to maximize the differences between their costs and their revenues. These production levels can be determined separately for each agent, so none need pay attention to what the others are doing; each agent treats her counterparts as passive features of the environment. The other kind of situation to which classical economic analysis can be applied without recourse to game theory is that of monopoly. Here, quite obviously, non-parametric considerations drop out, since there is only one agent under study. However, both perfect and monopolistic competition are very special and unusual market arrangements. Prior to the advent of game theory, therefore, economists were severely limited in the class of circumstances to which they could neatly apply their models.

Philosophers share with economists a professional interest in the conditions and techniques for the maximization of human welfare. In addition, philosophers have a special concern with the logical justification of actions, and often actions must be justified by reference to their expected outcomes. Without game theory, both of these problems resist analysis wherever non-parametric aspects are relevant. We will demonstrate this shortly by reference to the most famous (though not the most typical) game, the so-called *Prisoner's Dilemma*, and to other, more typical, games. In doing this, we will need to introduce, define and illustrate the basic elements and techniques of game theory. To this job we therefore now turn.

2. Basic Elements and Assumptions of Game Theory

2.1 Utility

An agent is, by definition, an entity with *goals and preferences*. Game theorists, like economists and philosophers studying rational decision-making, describe these by means of an abstract concept called *utility*. This refers to the amount of satisfaction an agent derives from an object or an event, so that an agent who, for example, adores the taste of pickles would be said to associate high utility with them, while an agent who can take or leave them derives a lower level of utility from them. Examples of this kind suggest that 'utility' denotes a measure of subjective *psychological* fulfillment, and this is indeed how the concept was generally (though not always) interpreted prior to the 1930s. During that decade, however, economists and philosophers under the influence of behaviourism objected to the theoretical use of such unobservable entities as 'psychological fulfillment quotients.' The economist Paul Samuelson (1938) therefore set out to define utility in such a way that it becomes a purely technical concept. That is, when we say that an agent acts so as to maximize her utility, we mean by 'utility' simply whatever it is that the agent's behavior suggests her to consistently desire. If this looks circular to you, it should: theorists who follow Samuelson *intend* the statement 'agents act so as to maximize their utility' as a tautology. Like other tautologies occurring in the foundations of scientific theories, it is useful not in itself, but because it helps to fix our contexts of inquiry.

Though we might no longer be moved by scruples derived from *psychological* behaviorism, many theorists continue to follow Samuelson's way of understanding utility because they think it important that game theory apply to *any* kind of agent -- a person, a bear, a bee, a firm or a country -- and not just to agents with human minds. When such theorists say that agents act so as to maximize their utility, they want this to be part of the *definition* of what it is to be an agent, not an empirical claim about possible inner states and motivations. Samuelson's conception of utility, defined by way of *Revealed Preference Theory* (RPT) introduced in his classic paper (Samuelson (1938)) satisfies this demand.

Some other theorists understand the point of game theory differently. They view game theory as providing an explanatory account of strategic reasoning. For this idea to be applicable, we must suppose that agents at least sometimes do what they do in non-parametric settings *because* game-theoretic logic recommends certain actions as the rational ones. Still other theorists interpret game theory *normatively*, as advising agents on what to do in strategic contexts in order to maximize their utility. Fortunately for our purposes, all of these ways of thinking about the possible uses of game theory are compatible with the tautological interpretation of utility maximization. The philosophical differences are not idle from the perspective of the working game theorist, however. As we will see in a later section, those who hope to use game theory to explain strategic *reasoning*, as opposed to merely strategic *behavior*, face some special philosophical and practical problems.

Since game theory involves formal reasoning, we must have a device for thinking of utility maximization in mathematical terms. Such a device is called a *utility function*. The utility-map for an agent is called a 'function' because it maps *ordered preferences* onto the real numbers. Suppose that agent *x* prefers bundle *a* to bundle *b* and bundle *b* to bundle *c*. We then map these onto a list of numbers, where the function maps the highest-ranked bundle onto the largest number in the list, the second-highest-ranked bundle onto the next-largest number in the list, and so on, thus:

bundle *a* » 3

bundle *b* » 2

bundle *c* » 1

The only property mapped by this function is *order*. The magnitudes of the numbers are irrelevant; that is, it must not be inferred that *x* gets 3 times as much utility from bundle *a* as she gets from bundle *c*. Thus we could represent *exactly the same* utility function as that above by

bundle *a* » 7,326

bundle *b* » 12.6

bundle *c* » -1,000,000

The numbers featuring in an ordinal utility function are thus not measuring any *quantity* of anything. A utility-function in which magnitudes *do* matter is called 'cardinal'. Whenever someone refers to a utility function without specifying which kind is meant, you should assume that it's ordinal. These are the sorts we'll need for the first set of games we'll examine. Later, when we come to seeing how to solve games that involve *randomization* -- our river-crossing game from Part 1 above, for example -- we'll need to build cardinal utility functions. The technique for doing this was given by von Neumann & Morgenstern (1947), and was an essential aspect of their invention of game theory. For the moment, however, we will need only ordinal functions.

2.2 Games and Information

All situations in which at least one agent can only act to maximize his utility through anticipating the responses to his actions by one or more other agents is called a *game*. Agents involved in games are referred to as *players*. If all agents have optimal actions regardless of what the others do, as in purely parametric situations or conditions of monopoly or perfect competition (see Section 1 above) we can model this without appeal to game theory; otherwise, we need it.

We assume that players are economically rational. That is, a player can (i) assess outcomes; (ii) calculate

paths to outcomes; and (iii) choose actions that yield their most-preferred outcomes, given the actions of the other players. This rationality might in some cases be internally computed by the agent. In other cases, it might simply be embodied in behavioral dispositions built by natural, cultural or economic selection.

Each player in a game faces a choice among two or more possible *strategies*. A strategy is a predetermined 'programme of play' that tells her what actions to take in response to *every possible strategy other players might use*. The significance of the italicized phrase here will become clear when we take up some sample games below.

A crucial aspect of the specification of a game involves the information that players have when they choose strategies. The simplest games (from the perspective of logical structure) are those in which agents have *perfect information*, meaning that at every point where each agent's strategy tells her to take an action, she knows everything that has happened in the game up to that point. A board-game of sequential moves in which in which both players watch all the action (and know the rules in common), such as chess, is an instance of such a game. By contrast, the example of the bridge-crossing game from Section 1 above illustrates a game of *imperfect information*, since the fugitive must choose a bridge to cross without knowing the bridge at which the pursuer has chosen to wait, and the pursuer similarly makes her decision in ignorance of the actions of her quarry. Since game theory is about rational action given the strategically significant actions of others, it should not surprise you to be told that what agents in games know, or fail to know, about each others' actions makes a considerable difference to the logic of our analyses, as we will see.

2.3 Trees and Matrices

The difference between games of perfect and of imperfect information is closely related to (though certainly not identical with!) a distinction between *ways of representing* games that is based on *order of play*. Let us begin by distinguishing between sequential-move and simultaneous-move games in terms of information. It is natural, as a first approximation, to think of sequential-move games as being ones in which players choose their strategies one after the other, and of simultaneous-move games as ones in which players choose their strategies at the same time. This isn't quite right, however, because what is of strategic importance is not the temporal *order* of events per se, but whether and when players *know about* other players' actions relative to having to choose their own. For example, if two competing businesses are both planning marketing campaigns, one might commit to its strategy months before the other does; but if neither knows what the other has committed to or will commit to when they make their decisions, this is a simultaneous-move game. Chess, by contrast, is normally played as a sequential-move game: you see what your opponent has done before choosing your own next action. (Chess *can* be turned into a simultaneous-move game if the players each call moves while isolated from the common board; but this is a very different game from conventional chess.)

It was said above that the distinction between sequential-move and simultaneous-move games is not identical to the distinction between perfect-information and imperfect-information games. Explaining why this is so is a good way of establishing full understanding of both sets of concepts. As simultaneous-

move games were characterized in the previous paragraph, it must be true that all simultaneous-move games are games of imperfect information. However, some games may contain mixes of sequential and simultaneous moves. For example, two firms might commit to their marketing strategies independently and in secrecy from one another, but thereafter engage in pricing competition in full view of one another. If the optimal marketing strategies were partially or wholly dependent on what was expected to happen in the subsequent pricing game, then the two stages would need to be analyzed as a single game, in which a stage of sequential play followed a stage of simultaneous play. Whole games that involve mixed stages of this sort are games of imperfect information, however temporally staged they might be. Games of perfect information (as the name implies) denote cases where *no* moves are simultaneous (and where no player ever forgets what has gone before).

It was said above that games of perfect information are the (logically) simplest sorts of games. This is so because in such games (as long as the games are finite, that is, terminate after a known number of actions) players and analysts can use a straightforward procedure for predicting outcomes. A rational player in such a game chooses her first action by considering each series of responses and counter-responses that will result from each action open to her. She then asks herself which of the available final outcomes brings her the highest utility, and chooses the action that starts the chain leading to this outcome. This process is called *backward induction* (because the reasoning works backwards from eventual outcomes to present decision problems).

We will have much more to say about backward induction and its properties in a later section (when we come to discuss equilibrium and equilibrium selection). For now, we have described it just in order to use it to introduce one of the two types of mathematical objects used to represent games: *game-trees*. A game-tree is an example of what mathematicians call a *directed graph*. That is, it is a set of connected nodes in which the overall graph has a direction. We can draw trees from the top of the page to the bottom, or from left to right. In the first case, nodes at the top of the page are interpreted as coming earlier in the sequence of actions. In the case of a tree drawn from left to right, leftward nodes are prior in the sequence to rightward ones. An unlabelled tree has a structure of the following sort:

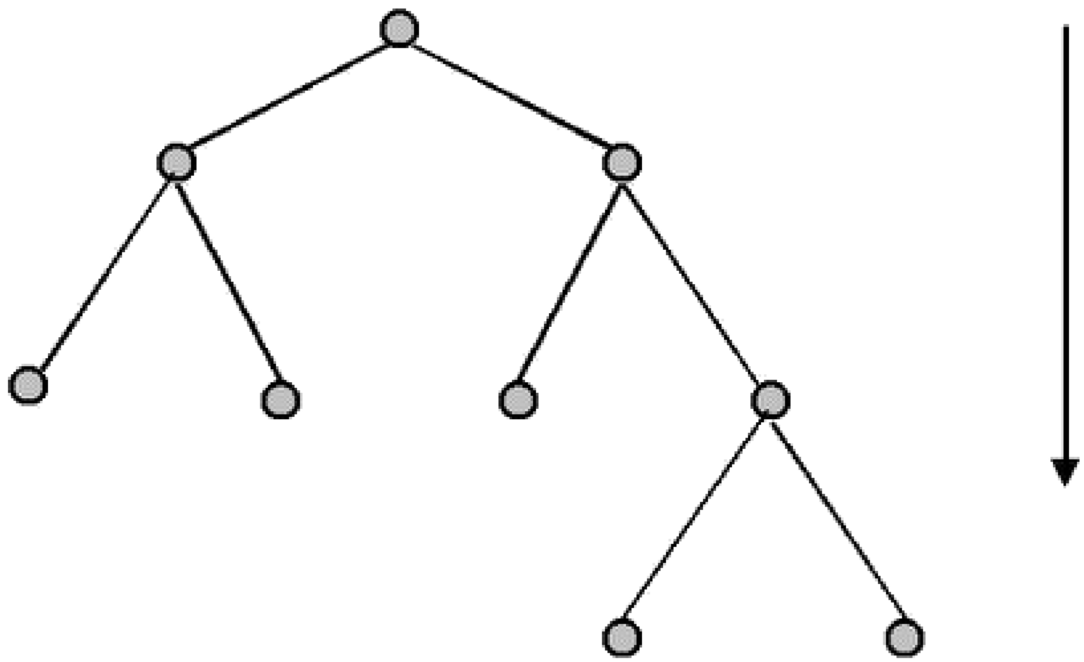

Figure 1

The point of representing games using trees can best be grasped by visualizing the use of them in supporting backward-induction reasoning. Just imagine the player (or analyst) beginning at the end of the tree, where outcomes are displayed, and then working backwards from these, looking for sets of strategies that describe paths leading to them. Since a player's utility function indicates which outcomes she prefers to which, we also know which paths she will prefer. Of course, not all paths will be possible because the other player has a role in selecting paths too, and won't take actions that lead to less preferred outcomes for him. We will present some examples of this interactive path-selection, and detailed techniques for reasoning through them, after we have described a situation we can use a tree to depict.

Trees are used to represent *sequential* games, because they show the order in which actions are taken by the players. However, games are sometimes represented on *matrices* rather than trees. This is the second type of mathematical object used to represent games. Matrices, unlike trees, simply show the outcomes, represented in terms of the players' utility functions, for every possible combination of strategies the players might use. For example, it makes sense to display the river-crossing game from Section 1 on a matrix, since in that game both the fugitive and the hunter have just one move each, and each chooses their move in ignorance of what the other has decided to do. Here, then, is *part of* the matrix:

		Hunter		
		Safe Bridge	Rocky Bridge	Cobra Bridge
Fugitive	Safe Bridge	0,1	1,0	1,0
	Rocky Bridge	?	0,1	?
	Cobra Bridge	?	?	0,1

Figure 2

The fugitive's three possible strategies -- cross at the safe bridge, risk the rocks and risk the cobras -- form the rows of the matrix. Similarly, the hunter's three possible strategies -- waiting at the safe bridge, waiting at the rocky bridge and waiting at the cobra bridge -- form the columns of the matrix. Each cell of the matrix shows -- or, rather *would* show if our matrix was complete -- an *outcome* defined in terms of the players' *payoffs*. A player's payoff is simply the number assigned by her ordinal utility function to the state of affairs corresponding to the outcome in question. For each outcome, Row's payoff is always listed first, followed by Column's. Thus, for example, the upper right-hand corner above shows that when the fugitive crosses at the safe bridge and the hunter is waiting there, the fugitive gets a payoff of 0 and the hunter gets a payoff of 1. We interpret these by reference to their utility functions, which in this game are very simple. If the fugitive gets safely across the river he receives a payoff of 1; if he doesn't he gets 0. If the fugitive doesn't make it, either because he's shot by the hunter or hit by a rock or struck by a cobra, then the hunter gets a payoff of 1 and the fugitive gets a payoff of 0.

We'll briefly explain the parts of the matrix that have been filled in, and then say why we can't yet complete the rest. Whenever the hunter waits at the bridge chosen by the fugitive, the fugitive is shot. These outcomes all deliver the payoff vector (0, 1). You can find them descending diagonally across the matrix above from the upper right-hand corner. Whenever the fugitive chooses the safe bridge but the hunter waits at another, the fugitive gets safely across, yielding the payoff vector (1, 0). These two outcomes are shown in the second two cells of the top row. All of the other cells are marked, *for now*, with question marks. Why? The problem here is that if the fugitive crosses at either the rocky bridge or the cobra bridge, he introduces parametric factors into the game. In these cases, he takes on some risk of getting killed, and so producing the payoff vector (0, 1), that is independent of anything the hunter does. We don't yet have enough concepts introduced to be able to show how to represent these outcomes in terms of utility functions -- but by the time we're finished we will, and this will provide the key to solving our puzzle from Section 1.

Matrix games are referred to as ‘normal-form’ or ‘strategic-form’ games, and games as trees are referred to as ‘extensive-form’ games. The two sorts of games are not equivalent, because extensive-form games contain information -- about sequences of play and players' levels of information about the game structure -- that strategic-form games do not. In general, a strategic-form game could represent any one of several extensive-form games, so a strategic-form game is best thought of as being a *set* of extensive-form games. When order of play is irrelevant to a game's outcome, then you should study its strategic form, since it's the whole set you want to know about. Where order of play *is* relevant, the extensive form *must* be specified or your conclusions will be unreliable.

2.4 The Prisoner's Dilemma as an Example of Strategic-Form vs. Extensive-Form Representation

The distinctions described above are difficult to fully grasp if all one has to go on are abstract descriptions. They're best illustrated by means of an example. For this purpose, we'll use the most famous game: the Prisoner's Dilemma. It in fact gives the logic of the problem faced by Cortez's and Henry V's soldiers (see Section 1 above), and by Hobbes's agents before they empower the tyrant. However, for reasons which will become clear a bit later, you should not take the PD as a *typical* game; it isn't. We use it as an extended example here only because it's particularly helpful for illustrating the *relationship* between strategic-form and extensive-form games (and later, for illustrating the relationships between one-shot and repeated games; see Section 4 below).

The name of the Prisoner's Dilemma game is derived from the following situation typically used to exemplify it. Suppose that the police have arrested two people whom they know have committed an armed robbery together. Unfortunately, they lack enough admissible evidence to get a jury to convict. They *do*, however, have enough evidence to send each prisoner away for two years for theft of the getaway car. The chief inspector now makes the following offer to each prisoner: If you will confess to the robbery, implicating your partner, and she does not also confess, then you'll go free and she'll get ten years. If you both confess, you'll each get 5 years. If neither of you confess, then you'll each get two years for the auto theft.

Our first step in modeling your situation as a game is to represent it in terms of utility functions. Both you and your partner's utility functions are identical:

Go free » 4

2 years » 3

5 years » 2

10 years » 0

The numbers in the function above are now used to express your and your partner's *payoffs* in the various outcomes possible in your situation. We will refer to you as 'Player I' and to your partner as 'Player II'. Now we can represent your entire situation on a matrix; this is the strategic form of your game:

Figure 3

Figure 3

Each cell of the matrix gives the payoffs to both players for each combination of actions. Player I's payoff appears as the first number of each pair, Player II's as the second. So, if both of you confess you each get a payoff of 2 (5 years in prison each). This appears in the upper-left cell. If neither of you confess, you each get a payoff of 3 (2 years in prison each). This appears as the lower-right cell. If you confess and your partner doesn't you get a payoff of 4 (going free) and she gets a payoff of 0 (ten years in prison). This appears in the upper-right cell. The reverse situation, in which she confesses and you refuse, appears in the lower-left cell.

You evaluate your two possible actions here by comparing your payoffs in each column, since this shows you which of your actions is preferable for each possible action by your partner. So, observe: If your partner confesses than you get a payoff of 2 by confessing and a payoff of 0 by refusing. If your partner refuses, you get a payoff of 4 by confessing and a payoff of 3 by refusing. Therefore, you're better off confessing regardless of what she does. Your partner, meanwhile, evaluates her actions by comparing her payoffs down each row, and she comes to exactly the same conclusion that you do. Wherever one action for a player is superior to her other actions for each possible action by the opponent, we say that the first action *strictly dominates* the second one. In the PD, then, confessing strictly dominates refusing for both players. Both players know this about each other, thus entirely eliminating any temptation to depart from the strictly dominated path. Thus both players will confess, and both will go to prison for 5 years.

The players, and analysts, can predict this outcome using a mechanical procedure, known as iterated elimination of strictly dominated strategies. You, as Player 1, can see by examining the matrix that your payoffs in each cell of the top row are higher than your payoffs in each corresponding cell of the bottom row. Therefore, it can never be rational for you to play your bottom-row strategy, viz., refusing to confess, *regardless of what your opponent does*. Since your bottom-row strategy will never be played, we can simply *delete* the bottom row from the matrix. Now it is obvious that Player II will not refuse to confess, since his payoff from confessing in the two cells that remain is higher than his payoff from refusing. So, once again, we can delete the one-cell column on the left from the game. We now have only one cell remaining, that corresponding to the outcome brought about by mutual confession. Since the reasoning that led us to delete all other possible outcomes depended at each step only on the premise that both players are economically rational - that is, prefer higher payoffs to lower ones - there is very strong grounds for viewing joint confession as the *solution* to the game, the outcome on which its play *must* converge. You should note that the order in which strictly dominated rows and columns are deleted doesn't matter. Had we begun by deleting the right-hand column and then deleted the bottom row, we would have arrived at the same solution.

It's been said a couple of times that the PD is not a typical game in many respects. One of these respects is

that all its rows and columns are either strictly dominated or strictly dominant. In any strategic-form game where this is true, iterated elimination of strictly dominated strategies is guaranteed to yield a unique solution. Later, however, we will see that for many games this condition does not apply, and then our analytic task is less straightforward.

You will probably have noticed something disturbing about the outcome of the PD. Had you both refused to confess, you'd have arrived at the lower-right outcome in which you each go to prison for only 2 years, thereby *both* earning higher utility than you receive when you confess. This is the most important fact about the PD, and its significance for game theory is quite general. We'll therefore return to it below when we discuss equilibrium concepts in game theory. For now, however, let us stay with our use of this particular game to illustrate the difference between strategic and extensive forms.

When people introduce the PD into popular discussions, you will sometimes hear them say that the police inspector must lock his prisoners into separate rooms so that they can't communicate with one another. The reasoning behind this idea seems obvious: if you could communicate, you'd surely see that you're both better off refusing, and could make an agreement to do so, no? This, one presumes, would remove your conviction that you must confess because you'll otherwise be sold up the river by your partner. In fact, however, this intuition is misleading and its conclusion is false.

When we represent the PD as a strategic-form game, we implicitly assume that the prisoners can't attempt collusive agreement since they choose their actions simultaneously. In this case, agreement before the fact can't help. If you are convinced that your partner will stick to the bargain then you can seize the opportunity to go scot-free by confessing. Of course, you realize that the same temptation will occur to her; but in that case you again want to make sure you confess, as this is your only means of avoiding your worst outcome. Your agreement comes to naught because you have no way of enforcing it; it constitutes what game theorists call ‘cheap talk’.

But now suppose that you do *not* move simultaneously. That is, suppose that one of you can choose *after* observing the other's action. This is the sort of situation that people who think non-communication important must have in mind. Now you can see that your partner has remained steadfast when it comes to your choice, and you need not be concerned about being suckered. However, this doesn't change anything, a point that is best made by re-representing the game in extensive form. This gives us our opportunity to introduce game-trees and the method of analysis appropriate to them.

First, however, here are definitions of some concepts that will be helpful in analyzing game-trees:

> *Node*: A point at which a player takes an action.
>
> *Initial node*: The point at which the first action in the game occurs.
>
> *Terminal node*: Any node which, if reached, ends the game. Each terminal node corresponds to an *outcome*.

Subgame: Any set of nodes and branches descending uniquely from one node.

Payoff: an ordinal utility number assigned to a player at an outcome.

Outcome: an assignment of a set of payoffs, one to each player in the game.

Strategy: a program instructing a player which action to take at every node in the tree where she could possibly be called on to make a choice.

These quick definitions may not mean very much to you until you follow them being put to use in our analyses of trees below. It will probably be best if you scroll back and forth between them and the examples as we work through them. By the time you understand each example, you'll find the concepts and their definitions quite natural and intuitive.

To make this exercise maximally instructive, let's suppose that you and your partner have studied the matrix above and, seeing that you're both better off in the outcome represented by the lower-right cell, have formed an agreement to cooperate. You are to commit to refusal first, at which point she will reciprocate. We will refer to a strategy of keeping the agreement as ‘cooperation’, and will denote it in the tree below with ‘C’. We will refer to a strategy of breaking the agreement as ‘defection’, and will denote it on the tree below with ‘D’. As before, you are I and your partner is II. Each node is numbered 1, 2, 3, ... , from top to bottom, for ease of reference in discussion. Here, then, is the tree:

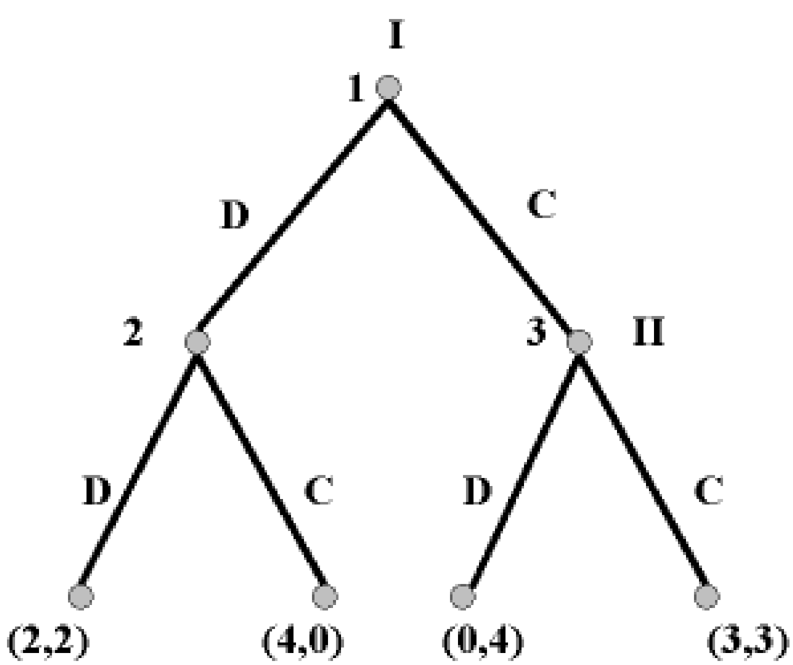

Figure 4

Look first at each of the terminal nodes (those along the bottom). These represent possible outcomes. Each is identified with a assignment of payoffs, just as in the strategic-form game, with I's payoff

appearing first in each set and II's appearing second. Each of the structures descending from the nodes 1, 2 and 3 respectively is a sub-game. We begin our backward-induction analysis -- using a technique called *Zermelo's algorithm* -- with the sub-games that arise last in the sequence of play. If the subgame descending from node 3 is played, then Player II will face a choice between a payoff of 4 and a payoff of 3. (Consult the second number, representing her payoff, in each set at a terminal node descending from node 3.) II earns her higher payoff by playing D. We may therefore replace the entire subgame with an assignment of the payoff (0, 4) directly to node 3, since this is the outcome that will be realized if the game reaches that node. Now consider the subgame descending from node 2. Here, II faces a choice between a payoff of 2 and one of 0. She obtains her higher one, 2, by playing D. We may therefore assign the payoff (2,2) directly to node 2. Now we move to the subgame descending from node 1. (This subgame is, of course, identical to the whole game; all games are subgames of themselves.) You (Player I) now face a choice between outcomes (2,2) and (0,4). Consulting the first numbers in each of these sets, you see that you get your higher payoff -- 2 -- by playing D. D is, of course, the option of confessing. So you confess, and then your partner also confesses, yielding the same outcome as in the strategic-form representation.

What has happened here is that you realize that if you play C (refuse to confess) at node 1, then your partner will be able to maximize her utility by suckering you and playing D. (On the tree, this happens at node 3.) This leaves you with a payoff of 0 (ten years in prison), which you can avoid only by playing D to begin with. You therefore defect from the agreement.

We have thus seen that in the case of the Prisoner's Dilemma, the simultaneous and sequential versions yield the same outcome. This will often not be true, however. In particular, only finite extensive-form (sequential) games of perfect information can be solved using Zermelo's algorithm.

As noted earlier in this section, sometimes we must represent simultaneous moves *within* games that are otherwise sequential. (As we said above, in all such cases the game as a whole will be one of imperfect information, so we won't be able to solve it using Zermelo's algorithm.) We represent such games using the device of *information sets*. Consider the following tree:

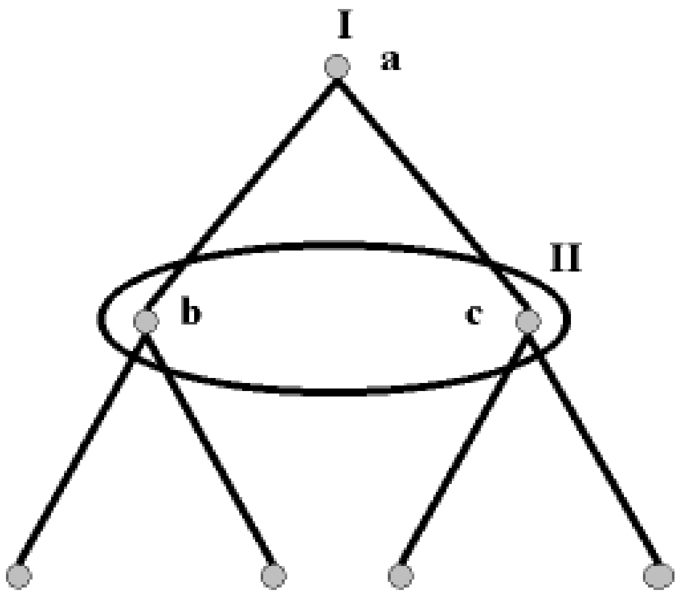

Figure 5

The oval drawn around nodes *b* and *c* indicates that they lie within a common information set. This means that at these nodes players cannot infer back up the path from whence they came; II does not know, in choosing her strategy, whether she is at *b* or *c*. (For this reason, what properly bear numbers in extensive-form games are information sets, conceived as ‘action points’, rather than nodes themselves; this is why the nodes inside the oval are labelled with letters rather than numbers.) Put another way, II, when choosing, does not know what I has done at node *a*. But you will recall from earlier in this section that this is just what defines two moves as simultaneous. We can thus see that the method of representing games as trees is entirely general. If no node after the initial node is alone in an information set on its tree, so that the game has only one subgame (itself), then the whole game is one of simultaneous play. If at least one node shares its information set with another, while others are alone, the game involves both simultaneous and sequential play, and so is still a game of imperfect information. Only if all information sets are inhabited by just one node do we have a game of perfect information.

2.5 Solution Concepts and Equilibria

In the Prisoner's Dilemma, the outcome we've represented as (2, 2), indicating mutual defection, was said to be the ‘solution’ to the game. Following the general practice in economics, game theorists refer to the solutions of games as *equilibria*. Philosophically minded readers will want to pose a conceptual question right here: What is ‘equilibrated’ about some game outcomes such that we are motivated to call them ‘solutions’? When we say that a physical system is in equilibrium, we mean that it is in a *stable* state, one in which all the causal forces internal to the system balance each other out and so leave it ‘at rest’ until and unless it is perturbed by the intervention of some exogenous (that is, ‘external’) force. This what economists have traditionally meant in talking about ‘equilibria’; they read economic systems as being networks of causal relations, just like physical systems, and the equilibria of such systems are then their endogenously stable states. As we will see after discussing evolutionary game theory in a later section, it is possible to maintain this understanding of equilibria in the case of game theory. However, as we noted

in Section 2.1, some people interpret game theory as being an explanatory theory of strategic reasoning. For them, a solution to a game must be an outcome that a rational agent would predict *using the mechanisms of rational computation alone*. Such theorists face some puzzles about solution concepts that aren't so important for the behaviorist. We will be visiting such puzzles and their possible solutions throughout the rest of this article.

It's useful to start the discussion here from the case of the Prisoner's Dilemma because it's unusually simple from the perspective of these puzzles. What we referred to as its 'solution' is the unique *Nash equilibrium* of the game. (The 'Nash' here refers to John Nash, the Nobel Prize-winning mathematician who in Nash (1950) did most to extend and generalize von Neumann & Morgenstern's pioneering work.) Nash equilibrium (henceforth 'NE') applies (or fails to apply, as the case may be) to whole *sets* of strategies, one for each player in a game. A set of strategies is a NE just in case no player could improve her payoff, given the strategies of all other players in the game, by changing her strategy. Notice how closely this idea is related to the idea of strict dominance: no strategy could be a NE strategy if it is strictly dominated. Therefore, if iterative elimination of strictly dominated strategies takes us to a unique outcome, we know we have found the game's unique NE. Now, almost all theorists agree that avoidance of strictly dominated strategies is a *minimum* requirement of rationality. This implies that *if* a game has an outcome that is a unique NE, as in the case of joint confession in the PD, that must be its unique solution. This is one of the most important respects in which the PD is an 'easy' (and atypical) game.

We can specify one class of games in which NE is always not only necessary but *sufficient* as a solution concept. These are finite perfect-information games that are also *zero-sum*. A zero-sum game (in the case of a game involving just two players) is one in which one player can only be made better off by making the other player worse off. (Tic-tac-toe is a simple example of such a game: any move that brings me closer to winning brings you closer to losing, and vice-versa.) We can determine whether a game is zero-sum by examining players' utility functions: in zero-sum games these will be mirror-images of each other, with one player's highly ranked outcomes being low-ranked for the other and vice-versa. In such a game, if I am playing a strategy such that, given your strategy, I can't do any better, and if you are *also* playing such a strategy, then, since any change of strategy by me would have to make you worse off and vice-versa, it follows that our game can have no solution compatible with our mutual rationality other than its unique NE. We can put this another way: in a zero-sum game, my playing a strategy that maximizes my minimum payoff if you play the best you can, and your simultaneously doing the same thing, is just *equivalent* to our both playing our best strategies, so this pair of so-called 'maximin' procedures is guaranteed to find the unique solution to the game, which is its unique NE. (In tic-tac-toe, this is a draw. You can't do any better than drawing, and neither can I, if both of us are trying to win and trying not to lose.)

However, most games do not have this property. It won't be possible, in this one article, to enumerate *all* of the ways in which games can be problematic from the perspective of their possible solutions. (For one thing, it is highly unlikely that theorists have yet discovered all of the possible problems!) However, we can try to generalize the issues a bit.

First, there is the problem that in most non-zero-sum games, there is more than one NE, but not all NE

look equally plausible as the solutions upon which strategically rational players would hit. Consider the strategic-form game below (taken from Kreps (1990), p. 403):

Figure 6

Figure 6

This game has two NE: s1-t1 and s2-t2. (Note that no rows or columns are strictly dominated here. But if Player I is playing s1 then Player II can do no better than t1, and vice-versa; and similarly for the s2-t2 pair.) If NE is our only solution concept, then we shall be forced to say that either of these outcomes is equally persuasive as a solution. However, if game theory is regarded as an explanatory and/or normative theory of strategic reasoning, this seems to be leaving something out: surely rational players with perfect information would converge on s1-t1? (Note that this is *not* like the situation in the PD, where the socially superior situation is unachievable because it is not a NE. In the case of the game above, both players have every reason to try to converge on the NE in which they are better off.)

This illustrates the fact that NE is a relatively (logically) *weak* solution concept, often failing to predict intuitively sensible solutions because, if applied alone, it refuses to allow players to use principles of equilibrium selection that, if not *demanded* by rationality, are at least not *irrational*. Consider another example from Kreps (1990), p. 397:

Figure 7

Figure 7

Here, no strategy strictly dominates another. However, Player I's top row, s1, *weakly* dominates s2, since I does *at least as well* using s1 as s2 for any reply by Player II, and on one reply by II (t2), I does better. So should not the players (and the analyst) delete the weakly dominated row s2? When they do so, column t1 is then strictly dominated, and the NE s1-t2 is selected as the unique solution. However, as Kreps goes on to show using this example, the idea that weakly dominated strategies should be deleted just like strict ones has odd consequences. Suppose we change the payoffs of the game just a bit, as follows:

Figure 8

Figure 8

s2 is still weakly dominated as before; but of our two NE, s2-t1 is now the most attractive for both players; so why should the analyst eliminate its possibility? (Note that this game, again, does *not* replicate the logic of the PD. There, it makes sense to eliminate the most attractive outcome, joint refusal to confess, because both players have incentives to unilaterally deviate from it, so it is not an NE. This is not true of s2-t1 in the present game. You should be starting to clearly see why we called the PD game 'atypical'.) The argument *for* eliminating weakly dominated strategies is that Player 1 may be nervous, fearing that Player II is not completely *sure* to be rational (or that Player II fears that Player I isn't completely rational, or that Player II fears that Player I fears that Player II isn't completely rational, and so

on ad infinitum) and so might play t2 with some positive probability. If the possibility of departures from rationality is taken seriously, then we have an argument for eliminating weakly dominated strategies: Player I thereby insures herself against her worst outcome, s2-t2. Of course, she pays a cost for this insurance, reducing her expected payoff from 10 to 5. On the other hand, we might imagine that the players could communicate before playing the game and agree play *correlated strategies* so as to *coordinate* on s2-t1, thereby removing some, most or all of the uncertainty that encourages elimination of the weakly dominated row s1, and eliminating s1-t2 as a viable NE instead!

Any proposed principle for solving games that may have the effect of eliminating one or more NE from consideration is referred to as a *refinement* of NE. In the case just discussed, elimination of weakly dominated strategies is one possible refinement, since it refines away the NE s2-t1, and correlation is another, since it refines away the other NE, s1-t2, instead. So which refinement is more appropriate as a solution concept? People who think of game theory as an explanatory and/or normative theory of strategic rationality have generated a substantial literature in which the merits and drawbacks of a large number of refinements are debated. In principle, there seems to be no limit on the number of refinements that could be considered, since there may also be no limits on the set of philosophical intuitions about what principles a rational agent might or might not see fit to follow or to fear or hope that other players are following.

Behaviorists take a dim view of much of this activity. They see the job of game theory as being to predict outcomes *given* some distribution of strategic dispositions, and some distribution of expectations about the strategic dispositions of others, that have been shaped by institutional processes and / or evolutionary selection. (See Section 7 for further discussion.) On this view, which NE are viable in a game is determined by the underlying dynamics that equipped players with dispositions *prior to* the commencement of a game. The strategic natures of players are thereby treated as a set of exogenous inputs to the game, just as utility functions are. Behaviorists are thus less inclined to seek *general* refinements of the equilibrium concept itself, at least insofar as these involve the modeling of *more sophisticated* expressions of rationality over and above merely consistent maximization of utility. Behaviorists are often inclined to doubt that the goal of seeking a *general* theory of rationality makes sense as a project. Institutions and evolutionary processes build many environments, and what counts as rational procedure in one environment may not be favoured in another. Economic rationality requires only that agents have consistent preferences, that is, that they not prefer *a* to *b* and *b* to *c* **and** *c* to *a*. A great many arrangements of strategic dispositions are compatible with this minimal requirement, and evolutionary or institutional processes might generate games in any of them. On this view, NE is a robust equilibrium concept because if players evolve their strategic dispositions in settings that are competitive, those who don't do what's optimal given the strategies of others *in that specific environment* will be outcompeted, and so selection will either eliminate them or encourage the learning of new dispositions. There is no more ‘refined’ concept of rationality of which this can be argued to be true *in general*; and so, according to behaviorists, refinements of NE based on refinements of rationality are likely to be of merely occasional interest.

This does not imply that behaviorists abjure all ways of restricting sets of NE to plausible subsets. In particular, they tend to be sympathetic to approaches that shift emphasis from rationality itself onto

considerations of the informational dynamics of games. We should perhaps not be surprised that NE analysis alone often fails to tell us much of interest about strategic-form games (e.g., Figure 6 above), in which informational structure is suppressed. Equilibrium selection issues are often more fruitfully addressed in the context of extensive-form games.

2.6 Modular Rationality and Subgame Perfection

In order to deepen our understanding of extensive-form games, we need an example with more interesting structure than the PD offers.

Consider the game described by this tree:

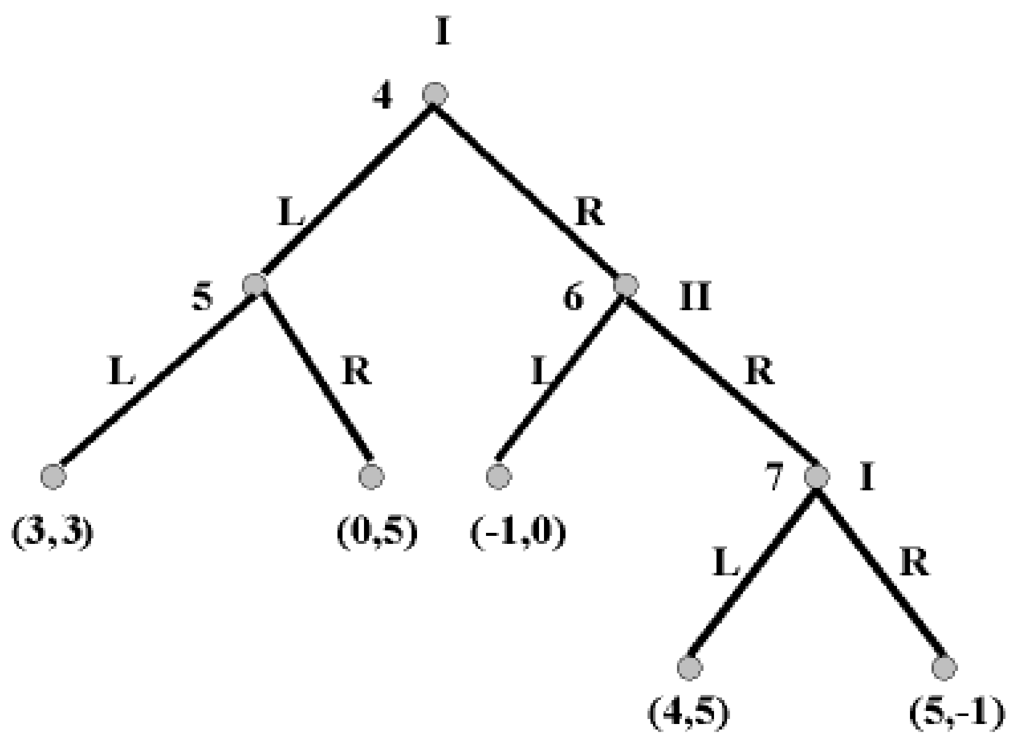

Figure 9

This game is not intended to fit any preconceived situation; it is simply a mathematical object in search of an application. (L and R here just denote ‘left’ and ‘right’ respectively.)

Now consider the strategic form of this game:

		II			
		LL	LR	RL	RR
I	LL	3,3	3,3	0,5	0,5
	LR	3,3	3,3	0,5	0,5
	RL	-1,0	4,5	-1,0	4,5
	RR	-1,0	5,-1	-1,0	5,-1

Figure 10

(If you are confused by this, remember that a strategy must tell a player what to do at *every* information set where that player has an action. Since each player chooses between two actions at each of two information sets here, each player has four strategies in total. The first letter in each strategy designation tells each player what to do if he or she reaches their first information set, the second what to do if their second information set is reached. I.e., LR for Player II tells II to play L if information set 5 is reached and R if information set 6 is reached.) If you examine this matrix, you will discover that (LL, RL) is among the NE. This is a bit puzzling, since if Player I reaches her second information set (7) in the extensive-form game, I would hardly wish to play L there; she earns a higher payoff by playing R at node 7. Mere NE analysis doesn't notice this because NE is insensitive to what happens *off the path of play*. Player I, in choosing L at node 4, ensures that node 7 will not be reached; this is what is meant by saying that it is ‘off the path of play’. In analyzing extensive-form games, however, we *should* care what happens off the path of play, because consideration of this is crucial to what happens *on* the path. For example, it is the fact that Player I *would* play R if node 7 were reached that *would* cause Player II to play L if node 6 were reached, and this is why Player I won't choose R at node 4. We are throwing away information relevant to game solutions if we ignore off-path outcomes, as mere NE analysis does. Notice that this reason for doubting that NE is a wholly satisfactory equilibrium concept in itself has nothing to do with intuitions about rationality, as in the case of the refinement concepts discussed in Section 2.5.

Now apply Zermelo's algorithm to the extensive form of our current example. Begin, again, with the last subgame, that descending from node 7. This is Player I's move, and she would choose R because she prefers her payoff of 5 to the payoff of 4 she gets by playing L. Therefore, we assign the payoff (5, -1) to node 7. Thus at node 6 II faces a choice between (-1, 0) and (5, -1). He chooses L. At node 5 II chooses R. At node 4 I is thus choosing between (0, 5) and (-1, 0), and so plays L. Note that, as in the PD, an outcome appears at a terminal node -- (4, 5) from node 7 -- that is Pareto superior to the NE. Again, however, the dynamics of the game prevent it from being reached.

The fact that Zermelo's algorithm picks out the strategy vector (LR, RL) as the unique solution to the game shows that it's yielding something other than just an NE. In fact, it is generating the game's *subgame*

perfect equilibrium (SPE). It gives an outcome that yields a NE not just in the *whole* game but in every subgame as well. This is an extremely persuasive solution concept because, again unlike the refinements of Section 2.5, it does not demand 'more' rationality of agents, but *less*. The agents, at every node, simply choose the path that brings them the highest payoff *in the subgame emanating from that node*; and, then, in solving the game, they foresee that they will all do that. Agents who proceed in this way are said to be *modular rational*, that is, short-run rational at each step. They do not imagine themselves, by some fancy processes of hyper-rationality, acting against their local preferences for the sake of some wider goal. Note that, as in the PD, this can lead to outcomes which might be regretted from the social point of view. In our current example, Player I would be better off, and Player II no worse off, at the left-hand node emanating from node 7 than at the SPE outcome. But Player I's very modular rationality, and Player II's awareness of this, blocks the socially efficient outcome. If our players wish to bring about the more equitable outcome (4,5) here, they must do so by redesigning their institutions so as to change the structures of the games they play. Merely wishing that they could be hyper-rational in some way does not seem altogether coherent as an approach.

2.7 On Interpreting Payoffs: Morality and Efficiency in Games

Many readers might suppose that the conclusion of the previous section has been asserted on the basis of no adequate defense. Surely, the players might be able to just *see* that outcome (4,5) is socially and morally superior; and since we know they can also see the path of actions that leads to it, who is the game theorist to announce that, within the game they're playing, it's unattainable? In fact, to suggest that hyper-rationality is a will o' the wisp *is* philosophically tendentious, though it is indeed what behaviorists about game theory believe. The reader who seeks a thorough justification for this belief is referred to Binmore (1994, 1998). However, before we just leave matters at a stand-off (here), we must be careful not to confuse what is controversial with the consequences of a simple technical mistake. Consider the Prisoner's Dilemma again. We have seen that in the unique NE of the PD, both players get less utility than they could have through mutual cooperation. This may struck you (as it has struck many commentators) as perverse. Surely, you may think, it simply results from a combination of selfishness and paranoia on the part of the players. To begin with they have no regard for the social good, and then they shoot themselves in the feet by being too untrustworthy to respect agreements.

This way of thinking leads to serious misunderstandings of game theory, and so must be dispelled. Let us first introduce some terminology for talking about outcomes. Welfare economists typically measure social good in terms of *Pareto efficiency*. A distribution of utility β is said to be *Pareto dominant* over another distribution δ just in case from state δ there is a possible redistribution of utility to β such that at least one player is better off in β than in δ and no player is worse off. Failure to move to a Pareto-dominant redistribution is *inefficient* because the existence of β as a logical possibility shows that in δ some utility is being wasted. Now, the outcome (3,3) that represents mutual cooperation in our model of the PD is clearly Pareto dominant over mutual defection; at (3,3) *both* players are better off than at (2,2). So it is true that PDs lead to inefficient outcomes. This was true of our example in Section 2.6 as well.

However, inefficiency should not be associated with immorality. A utility function for a player is

supposed to represent *everything that player cares about*, which may be anything at all. As we have described the situation of our prisoners they do indeed care only about their own relative prison sentences, but there is nothing essential in this. What makes a game an instance of the PD is strictly and only its payoff structure. Thus we could have two Mother Theresa types here, both of whom care little for themselves and wish only to feed starving children. But suppose the original Mother Theresa wishes to feed the children of Calcutta while Mother Juanita wishes to feed the children of Bogota. And suppose that the international aid agency will maximize its donation if the two saints nominate the same city, will give the second-highest amount if they nominate each others' cities, and the lowest amount if they each nominate their own city. Our saints are in a PD here, though hardly selfish or unconcerned with the social good.

To return to our prisoners, suppose that, contrary to our assumptions, they *do* value each other's well-being as well as their own. In that case, this must be reflected in their utility functions, and hence in their payoffs. If their payoff structures are changed, they will no longer be in a PD. But all this shows is that not every possible situation is a PD; it does *not* show that the threat of inefficient outcomes is a special artifact of selfishness. It is the *logic* of the prisoners' situation, not their psychology, that traps them in the inefficient outcome, and if that really *is* their situation then they are stuck in it (barring further complications to be discussed below). Agents who wish to avoid inefficient outcomes are best advised to prevent certain games from arising; the defender of the possibility of hyper-rationality is really proposing that they try to dig themselves out of such games by turning themselves into different kinds of agents.

In general, then, a game is partly *defined* by the payoffs assigned to the players. If a proposed solution involves tacitly changing these payoffs, then this ‘solution’ is in fact a disguised way of changing the subject.

2.8 Trembling Hands

Our last point above opens the way to a philosophical puzzle, one of several that still preoccupy those concerned with the logical foundations of game theory. It can be raised with respect to any number of examples, but we will borrow an elegant one from C. Bicchieri (1993), who also provides the most extensive treatment of the problem found in the literature. Consider the following game:

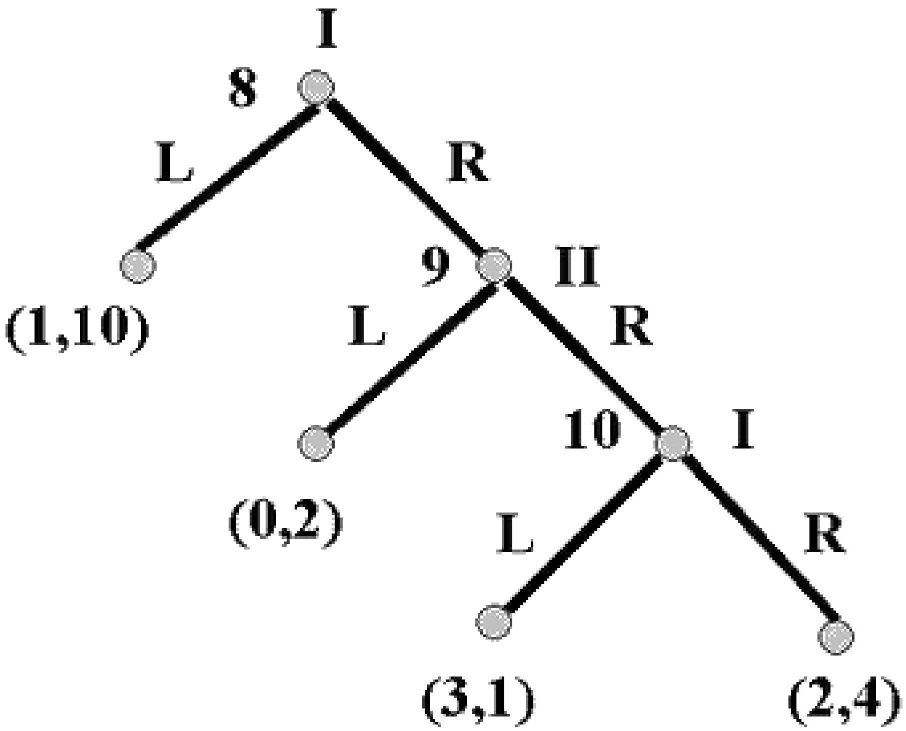

Figure 11

The NE outcome here is at the single leftmost node descending from node 8. To see this, backward induct again. At node 10, I would play L for a payoff of 3, giving II a payoff of 1. II can do better than this by playing L at node 9, giving I a payoff of 0. I can do better than this by playing L at node 8; so that is what I does, and the game terminates without II getting to move. But, now, notice the reasoning required to support this prediction. I plays L at node 8 because she knows that II is rational, and so would, at node 9, play L because II knows that I is rational and so would, at node 10, play L. But now we have the following paradox: I must suppose that II, at node 9, would predict I's rational play at node 10 despite having arrived at a node (9) that could only be reached if I is not rational! If I is not rational then II is not justified in predicting that I will not play R at node 10, in which case it is not clear that II shouldn't play R at 9; and if II plays R at 9, then I is guaranteed of a better payoff then she gets if she plays L at node 8. Both players must use backward induction to solve the game; backward induction requires that I know that II knows that I is rational; but II can solve the game only by using a backward induction argument that takes as a premise the irrationality of I. This is the *paradox of backward induction*.

A standard way around this paradox in the literature is to invoke the so-called ‘trembling hand’ due to Selten (1975). The idea here is that a decision and its consequent act may ‘come apart’ with some nonzero probability, however small. That is, a player might intend to take an action but then slip up in the execution and send the game down some other path instead. If there is even a remote possibility that a player may make a mistake -- that her ‘hand may tremble’ -- then no contradiction is introduced by a player's using a backward induction argument that requires the hypothetical assumption that another player has taken a path that a rational player could not choose. In our example, II could reason about what to do at node 9 conditional on the assumption that I rationally chose L at node 8 but then slipped.

There is a substantial technical literature on this backward-induction paradox, of which Bicchieri (1993)

is the most comprehensive source. (Bicchieri, it should be noted, does *not* endorse an appeal to trembling hands as the appropriate solution. Discussing her particular proposal here would, however, take us too far afield into technicalities. The interested reader should study her book.) The puzzle has been introduced here just in order to point out that refinements of the type discussed in Section 2.6 can be encouraged by more than mere intuitions about the concept of rationality. For if hands may tremble than merely economically rational players *will* be motivated to worry about the probabilities with which apparent departures from rational play will be observed. For example, if my opponent's hand may tremble, then this gives me good reason to avoid the weakly dominated strategy s2 in the third example from Section 2.5. After all, my opponent might promise to play t1 in that game, and I may believe his promise; but if his hand then trembles and a play of t2 results, I get my worst payoff. If I'm risk-averse, then in such situations it would seem that I should stick to weakly dominant strategies.

The reader won't be surprised to hear that the behaviorist has a reply to this. He argues that when a player considers what would happen at nodes reachable only along out-of-equilibrium paths, he need merely refer to *possible worlds* in which the subgames beginning at the nodes in question exist by themselves (i.e., detached from the remainders of the games in which they occur). This might seem like an ad hoc resort; but it is not clear that it is any *less* so than is appeal to trembling hands, which find no independent motivation from elsewhere in economic theory or the theory of rational choice. In any case, appeal to possible worlds is a common strategy in science according to many philosophers. The issue is raised here not with any hope in mind of saying something conclusive about it, but just to give the reader some further sense of the philosophical issues that generate controversy in the foundations of game theory.

3. Uncertainty, Risk and Sequential Equilibria

The games we've modeled to this point have all involved players choosing from amongst *pure strategies*, in which each seeks a single optimal course of action at each node that constitutes a best reply to the rational actions of others. Often, however, a player's utility is optimized through use of a *mixed* strategy, in which she flips a weighted coin amongst several possible actions. (We will see later that there is an alternative interpretation of mixing, not involving randomization at a particular information set; but we will start here from the coin-flipping interpretation and then build on it in Section 3.1.) Mixing is necessary whenever maximization of the player's utility depends on creating *uncertainty* in the expectations of her opponent. Our river-crossing game from Section 1 exemplifies this. As we saw, the puzzle in that game consists in the fact that if the fugitive's reasoning selects a particular bridge as optimal, his pursuer must be assumed to be able to duplicate that reasoning. Thus the fugitive can escape only if his pursuer is surprised. But symmetry of logical reasoning power on the part of the two players ensures that the fugitive can surprise the pursuer only if he succeeds in surprising *himself*.

Suppose that we ignore rocks and cobras for a moment, and imagine that the bridges are equally safe. In this case, the fugitive's best course is to roll a three-sided die, in which each side represents a different bridge (or, more conventionally, a six-sided die in which each bridge is represented by two sides). He must then pre-commit himself to using whichever bridge is selected by this *randomizing device*. Against this strategy, the pursuer's best reply is to also use a three-sided die of her own. The fugitive now has a

2/3 probability of escaping and the pursuer a 1/3 probability of catching him. The fugitive cannot improve on these odds if the pursuer is randomizing, since to favour one bridge merely provides the pursuer with a pattern that can be exploited. Identical reasoning applies to the pursuer. Therefore, the two randomizing strategies are best replies to one another, and are therefore in Nash equilibrium.

Now let us re-introduce the parametric factors, that is, the falling rocks at bridge #2 and the cobras at bridge #3. Again, suppose that bridge #3 (cobras) is four times more dangerous for the fugitive than bridge #2 (rocks), while bridge #2 is 20% more dangerous than bridge #1 (unobstructed). We can solve this new game *if* we make certain assumptions about the two players' utility functions. Suppose that Player 1, the fugitive, cares only about living or dying (preferring life to death) while the pursuer simply wishes to be able to report that the fugitive is dead, preferring this to having to report that he got away. (In other words, neither player cares about *how* the fugitive lives or dies.) In this case, the fugitive simply takes his original randomizing formula and weights it according to the different levels of parametric danger at the three bridges. Each bridge should be thought of as a *lottery* over the fugitive's possible outcomes, in which each lottery has a different *expected payoff* in terms of the items in his utility function.

Consider matters from the pursuer's point of view. She will be using her NE strategy when she chooses the mix of probabilities over the three bridges that makes the fugitive indifferent amongst them as crossing points. The bridge with rocks is 1.2 times more dangerous for him than the safe bridge. Therefore, he will be indifferent between the two when the pursuer is 1.2 times more likely to be waiting at the rocky bridge than the safe bridge. The cobra bridge is 4 times more dangerous for the fugitive than the rocky bridge. Therefore, he will be indifferent between these two bridges when the pursuer's probability of waiting at the rocky bridge is 4 times higher than the probability that she is at the cobra bridge. This gives us an indifference ratio amongst the bridges of 4.8:4:1. Suppose that no mixed strategy involving use of the cobra bridge is dominated by a mixed strategy involving use of only the other two bridges (i.e., that the cobra bridge is not so dangerous that the hunter can't make the fugitive indifferent between its use and that of the other at any value). Since the probabilities must sum to 100, we find the probability with which the pursuer waits at each bridge by solving the following equation:

$$4.8x + 4x + x = 100$$

x here equals 10.2. So at Nash equilibrium the pursuer must appear at the cobra bridge with a probability of .102, at the rocky bridge with a probability of .408, and the safe bridge with a probability of .489. These probabilities tell her how to weight her die before throwing it. The fugitive's NE strategy is, of course, as before: knowing that the pursuer will randomize so as to leave him indifferent, he will choose each bridge with equal probability.

We were able to solve this game straightforwardly because we set the utility functions in such a way as to make it *zero-sum*, or *strictly competitive*. That is, every gain in expected utility by one player represents a precisely symmetrical loss by the other. However, this condition may often not hold. Suppose now that the utility functions are more complicated. The pursuer most prefers an outcome in which she shoots the fugitive and so claims credit for his apprehension to one in which he dies of rockfall or snakebite; and she

prefers this second outcome to his escape. The fugitive prefers a quick death by gunshot to the pain of being crushed or the terror of an encounter with a cobra. Most of all, of course, he prefers to escape. We cannot solve this game, as before, simply on the basis of knowing the players' ordinal utility functions, since the *intensities* of their respective preferences will now be relevant to their strategies.

Prior to the work of von Neumann & Morgenstern (1947), situations of this sort were inherently baffling to analysts. This is because utility does not denote a hidden psychological variable such as *pleasure*. As we discussed in Section 2.1, utility is merely a measure of relative behavioural dispositions given certain consistency assumptions about relations between preferences and choices. It therefore makes no sense to imagine comparing our players' *cardinal* -- that is, intensity-sensitive -- preferences with one another's, since there is no independent, interpersonally constant yardstick we could use. How, then, can we model games in which cardinal information is relevant? After all, modeling games requires that all players' utilities be taken simultaneously into account, as we've seen.

A crucial aspect of von Neumann & Morgenstern's (1947) work was the solution to this problem. Here, we will provide a brief outline of their ingenious technique for building cardinal utility functions out of ordinal ones. It is emphasized that what follows is merely an *outline*, so as to make cardinal utility non-mysterious to you as a student who is interested in knowing about the philosophical foundations of game theory, and about the range of problems to which it can be applied. Providing a manual you could follow in *building* your own cardinal utility functions would require many pages. Fortunately, such manuals are available in many textbooks. In any case, if you are a philosophy student you may not wish to attempt this until you've taken a course in probability theory.

Suppose we have an agent whose ordinal utility function is known. Indeed, suppose that it's our river-crossing fugitive. Let's assign him the following ordinal utility function:

Escape » 4

Death by shooting » 3

Death by rockfall » 2

Death by snakebite » 1

Now, we know that his preference for escape over *any* form of death is likely to be stronger than his preference for, say, shooting over snakebite. This should be reflected in his choice behaviour in the following way. In a situation such as the river-crossing game, he should be willing to run greater risks to increase the relative probability of escape over shooting than he is to increase the relative probability of shooting over snakebite. This bit of logic is the crucial insight behind von Neumann & Morgenstern's (1947) solution to the cardinalization problem.

Begin by asking our agent to pick, from the available set of outcomes, a *best* one and a *worst* one. ‘Best’

and ‘worst’ are defined in terms of rational choice: a rational agent always chooses so as to maximize the probability of the best outcome -- call this **W** -- and to minimize the probability of the worst outcome -- call this **L**. Now consider prizes intermediate between **W** and **L**. We find, for a set of outcomes containing such prizes, a lottery over them such that our agent is indifferent between that lottery and a lottery including only **W** and **L**. In our example, this would be a lottery having shooting and rockfall as its possible outcomes. Call this lottery **T** . We define a utility function $q = u(\mathbf{T})$ such that if q is the expected prize in **T** , the agent is indifferent between winning **T** and winning a lottery in which **W** occurs with probability $u(\mathbf{T})$ and **L** occurs with probability $1 - u(\mathbf{T})$.

We now construct a *compound lottery* **T*** over the outcome set {**W**, **L**} such that the agent is indifferent between **T** and **T***. A compound lottery is one in which the prize in the lottery is another lottery. This makes sense because, after all, it is still **W** and **L** that are at stake for our agent in both cases; so we can then analyze **T*** into a simple lottery over **W** and **L**. Call this lottery **r**. It follows from transitivity that **T** is equivalent to **r**. (Note that this presupposes that our agent does not gain utility from the complexity of her gambles.) The rational agent will now choose the action that maximizes the probability of winning **W**. The mapping from the set of outcomes to $u(\mathbf{r})$ is a *von Neumann-Morgenstern utility function* (VNMuf).

What exactly have we done here? We've simply given our agent choices over lotteries, instead of over prizes directly, and observed how much extra risk he's willing to run to increase the chances of winning escape over snakebite relative to getting shot or clobbered with a rock. A VNMuf yields a *cardinal*, rather than an ordinal, measure of utility. Our choice of endpoint-values, **W** and **L**, is arbitrary, as before; but once these are fixed the values of the intermediate points are determined. Therefore, the VNMuf *does* measure the relative preference intensities of a single agent. However, since our assignment of utility values to **W** and **L** *is* arbitrary, we can't use VNMufs to compare the cardinal preferences of one agent with those of another. Furthermore, since we are using a *risk-metric* as our measuring instrument, the construction of the new utility function depends on assuming that our agent's *attitude to risk itself* stays constant from one comparison of lotteries to another. This seems reasonable for a single agent in a single game-situation. However, two agents in one game, or one agent under different sorts of circumstances, may display very different attitudes to risk. Perhaps in the river-crossing game the pursuer, whose life is not at stake, will enjoy gambling with her glory while our fugitive is cautious. In general, a *risk-averse* agent prefers a guaranteed prize to its equivalent expected value in a lottery. A *risk-loving* agent has the reverse preference. A *risk-neutral* agent is indifferent between these options. In analyzing the river-crossing game, however, we don't *have to* be able to compare the pursuer's cardinal utilities with the fugitive's. Both agents, after all, can find their NE strategies if they can estimate the probabilities each will assign to the actions of the other. This means that each must know both VNMufs; but neither need try to comparatively value the outcomes over which they're gambling.

We can now fill in the rest of the matrix for the bridge-crossing game that we started to draw in Section 2. If all that the fugitive cares about is life and death, but not the manner of death, and if all the hunter cares about is preventing the fugitive from escaping, then we can now interpret both utility functions cardinally. This permits us to assign expected utilities, expressed by multiplying the original payoffs by the relevant probabilities, as outcomes in the matrix. Suppose that the hunter waits at the cobra bridge with probability x and at the rocky bridge with probability y. Since her probabilities across the three bridges must sum to

1, this implies that she must wait at the safe bridge with probability $1 - (x + y)$. Then, continuing to assign the fugitive a payoff of 0 if he dies and 1 if he escapes, and the hunter the reverse payoffs, our complete matrix is as follows:

Figure 12

Figure 12

We can now read the following facts about the game directly from the matrix. No rows or columns strictly or weakly dominate any others. Therefore, the game's NE must be in mixed strategies.

3.1 Beliefs

Here is an odd feature of our analysis of the river-crossing game above. In the situation as we have imagined it, the fugitive knows that the hunter is least likely to cross at the cobra bridge. Yet we have told her to select a bridge at which to wait by flipping a coin. This process gives a non-zero probability of selecting the cobra bridge. Yet, surely, if the coin selects the cobra bridge it cannot be rational for the hunter to do as it directs. Won't she feel like a bit of an idiot standing there, knowing that the fugitive is probably waltzing across the safe bridge, or the relatively safe rocky bridge? Note that she will *not* feel torn in this situation if she plays this game with fugitives on a regular basis (and they know this). In that case, it is perfectly reasonable that she must *sometimes* wait at the cobra bridge, lest all fugitives be able to do better than their odds at NE by using the cobra bridge more often. Now, as far as the behaviorist is concerned this ends the matter. If the hunter and the fugitive have regularly played games that structurally *resemble* this river-crossing game, then selection pressures will have encouraged habits in them that lead them both to play its NE strategies *and to sincerely rationalize doing so* by means of some satisfying story or other. If neither party has ever been in a situation like this, and if their biological and/or cultural ancestors haven't either, and if neither is concerned with revealing information to opponents in expected future situations of this sort, then their behavior should be predicted not by a game theorist but by friends of theirs who are familiar with their personal idiosyncracies. Behaviorists are happy to recognize that game theory isn't useful for every decision problem, or even every strategic decision problem, that comes along.

However, the philosopher who wants game theory to serve as a descriptive and/or normative theory of strategic rationality cannot rest content with this answer. He must find a satisfying line of advice for the players even when their game is alone in the universe of strategic problems. No such advice can be given that is *uncontroversially* satisfactory -- behaviorists, after all, are often behaviorists *because* they aren't satisfied by any available approach here -= but there is a way of handling the matter that many game theorists have found worthy of detailed pursuit. This involves the computation of *equilibria in beliefs*.

In fact, the behaviorist needs the concept of equilibrium in beliefs too, but for different purposes. As we've seen, the concept of NE sometimes doesn't go deep enough as an analytical instrument to tell us all that we think might be important in a game. Thus even behaviorists who aren't impressed with the project of refinements make frequent use of the concept of subgame-perfect equilibrium (SPE) as discussed in

Section 2.6. But now consider the three-player imperfect-information game below (taken from Kreps (1990), p. 426):

Figure 13

Figure 13

One of the NE of this game is Lr_2l_3. This is because if Player I plays L, then Player II playing r_2 has no incentive to change strategies because her only node of action, 12, is off the path of play. But this NE seems to be purely technical; it makes little sense as a solution. This reveals itself in the fact that if the game beginning at node 14 could be treated as a subgame, Lr_2l_3 would not be an SPE. Whenever she *does* get a move, Player II should play l_2. But if Player II is playing l_2 then Player I should switch to R. In that case Player III should switch to r_3, sending Player II back to r_2. And here's a new, ‘sensible’, NE: Rr_2r_3. I and II in effect play ‘keepaway’ from III; and so that's what we'll name this game.

This NE is ‘sensible’ in just the same way that a SPE outcome in a perfect-information game is more sensible than other non-SPE NE. However, we can't select it by applying Zermelo's algorithm. Because nodes 13 and 14 fall inside a common information set, Keepaway has only one subgame (namely, the whole game). We need a ‘cousin’ concept to SPE that we can apply in cases of imperfect information, and we need a new solution procedure to replace Zermelo's algorithm for such games.

Notice what Player III in Keepaway is wondering about as he selects his strategy. "Given that I get a move," he asks himself, "was my action node reached from node 11 or from node 12?" What, in other words, are the *conditional probabilities* that III is at node 13 or 14 given that he has a move? Now, if conditional probabilities are what III wonders about, then what Players I and II must make conjectures about when they select *their* strategies are III's *beliefs* about these conditional probabilities. In that case, I must conjecture about II's beliefs about III's beliefs, and III's beliefs about II's beliefs and so on. The relevant beliefs here are not merely strategic, as before, since they are not just about what players will *do* given a set of payoffs and game structures, but about what they think makes sense given some understanding or other of conditional probability.

What beliefs about conditional probability is it reasonable for players to expect from each other? The normative theorist might insist on whatever the best mathematicians have discovered about the subject. Clearly, however, if this is applied then a theory of games that incorporated it would not be descriptively true of most people. The behaviorist will insist on imposing only behavioral habits that a process of natural selection might build into its products. Perhaps some actual or possible creatures might observe habits that respect *Bayes's rule*, which is the minimal true generalization about conditional probability that an agent could know if it knows any such generalizations at all. Adding more sophisticated knowledge about conditional probability amounts to refining the concept of equilibrium-in-belief, just as some game theorists like to refine NE. You can imagine what behaviorists think of *that* project!

Here, we will restrict our attention to the least refined equilibrium-in-belief concept, that obtained when

we require players to reason in accordance with Bayes's rule. Bayes's rule tells us how to compute the probability of an event F given information E (written 'pr(F/E)'):

pr(F/E) = [pr(E/F) X pr(F)] / pr(E)

We will henceforth assume that players do not hold beliefs inconsistent with this equality.

We may now define a *sequential equilibrium*. A SE has two parts: (1) a strategy profile § for each player, as before, and (2) a *system of beliefs* μ for each player. μ assigns to each information set *h* a probability distribution over the nodes *x* in *h*, with the interpretation that these are the beliefs of player *i(h)* about where in his information set he is, given that information set *h* has been reached. Then a sequential equilibrium is a profile of strategies § and a system of beliefs μ consistent with Bayes's rule such that starting from every information set *h* in the tree player *i(h)* plays optimally from then on, given that what he believes to have transpired previously is given by μ(*h*) and what will transpire at subsequent moves is given by §.

We now demonstrate the concept by application to Keepaway. Consider again the uninteresting NE Lr_2l_3. Suppose that Player III assigns pr(1) to her belief that if she gets a move she is at node 13. Then Player II, given a consistent μ(II), must believe that III will play l_3, in which case her only SE strategy is l_2. So although Lr_2l_3 is a NE, it is not a SE. This is of course what we want.

The use of the consistency requirement in this example is somewhat trivial, so consider now a second case (also taken from Kreps (1990), p. 429):

Figure 14

Figure 14

Suppose that I plays L, II plays l_2 and III plays l_3. Suppose also that μ(II) assigns pr(.3) to node 16. In that case, l_2 is not a SE strategy for II, since l_2 returns an expected payoff of .3(4) + .7(2) = 2.6, while r_2 brings an expected payoff of 3.1. Notice that if we fiddle the strategy profile for player III while leaving everything else fixed, l_2 could *become* a SE strategy for II. If §(III) yielded a play of l_3 with pr(.5) and r_3 with pr(.5), then if II plays r_2 his expected payoff would now be 2.2, so Ll_2l_3 would be a SE. Now imagine setting μ(III) back as it was, but change μ(II) so that II thinks the conditional probability of being at node 16 is greater than .5; in that case, l_2 is again not a SE strategy.

The idea of SE is hopefully now clear. We can apply it to the river-crossing game in a way that avoids the necessity for the hunter to flip any coins of we modify the game a bit. Suppose now that II can change bridges twice during the fugitive's passage, and will catch him just in case she meets him as he leaves the bridge. Then the hunter's SE strategy is to divide her time at the three bridges in accordance with the proportion given by the equation in the third paragraph of Section 3 above.

It must be noted that since Bayes's rule cannot be applied to events with probability 0, its application to SE requires that players assign non-zero probabilities to all actions available in trees. This requirement is captured by supposing that all strategy profiles be *strictly mixed*, that is, that every action at every information set be taken with positive probability. You will see that this is just equivalent to supposing that all hands sometimes tremble. A SE is said to be *trembling-hand perfect* if all strategies played at equilibrium are best replies to strategies that are strictly mixed. You should also not be surprised to be told that no weakly dominated strategy can be trembling-hand perfect, since the possibility of trembling hands gives players the most persuasive reason for avoiding such strategies.

4. Repeated Games and Coordination

So far we've restricted our attention to *one-shot* games, that is, games in which players' strategic concerns extend no further than the terminal nodes of their single interaction. However, games are often played with *future* games in mind, and this can significantly alter their outcomes and equilibrium strategies. Our topic in this section is *repeated games*, that is, games in which sets of players expect to face each other in similar situations on multiple occasions. We approach these first through the limited context of repeated prisoner's dilemmas.

We've seen that in the one-shot PD the only NE is mutual defection. This may no longer hold, however, if the players expect to meet each other again in future PDs. Imagine that four firms, all making widgets, agree to maintain high prices by jointly restricting supply. (That is, they form a cartel.) This will only work if each firm maintains its agreed production quota. Typically, each firm can maximize its profit by departing from its quota while the others observe theirs, since it then sells more units at the higher market price brought about by the almost-intact cartel. In the one-shot case, all firms would share this incentive to defect and the cartel would immediately collapse. However, the firms expect to face each other in competition for a long period. In this case, each firm knows that if it breaks the cartel agreement, the others can punish it by underpricing it for a period long enough to more than eliminate its short-term gain. Of course, the punishing firms will take short-term losses too during their period of underpricing. But these losses may be worth taking if they serve to reestablish the cartel and bring about maximum long-term prices.

One simple, and famous (but *not*, contrary to widespread myth, necessarily optimal) strategy for preserving cooperation in repeated PDs is called *tit-for-tat*. This strategy tells each player to behave as follows:

i. Always cooperate in the first round.
ii. Thereafter, take whatever action your opponent took in the previous round.

A group of players *all* playing tit-for-tat will never see any defections. Since, in a population where others play tit-for-tat, tit-for-tat is the rational response for each player, everyone playing tit-for-tat is a NE. You may frequently hear people who know a *little* (but not enough) game theory talk as if this is the end of the story. It is not.

There are two complications. First, the players must be uncertain as to when their interaction ends. Suppose the players know when the last round comes. In that round, it will be rational for players to defect, since no punishment will be possible. Now consider the second-last round. In this round, players also face no punishment for defection, since they know they will defect in the last round anyway. So they defect in the second-last round. But this means they face no threat of punishment in the third-last round, and defect there too. We can simply iterate this backwards through the game tree until we reach the first round. Since cooperation is not rational in that round, tit-for-tat is no longer a rational strategy, and we get the same outcome -- mutual defection -- as in the one-shot PD. Therefore, cooperation is only possible in repeated PDs where the expected number of repetitions is indeterminate. (Of course, this does apply to many real-life games.)

But now we introduce a second complication. Suppose that players' ability to distinguish defection from cooperation is imperfect. Consider our case of the widget cartel. Suppose the players observe a fall in the market price of widgets. Perhaps this is because a cartel member cheated. Or perhaps it has resulted from an exogenous drop in demand. If tit-for-tat players mistake the second case for the first, they will defect, thereby setting off a chain-reaction of mutual defections from which they can *never* recover, since every player will reply to the first encountered defection with defection, thereby begetting further defections, and so on.

If players know that such miscommunication is possible, they must resort to more sophisticated strategies. In particular, they must be prepared to sometimes risk following defections with cooperation in order to test their inferences. However, they mustn't be *too* forgiving, lest other players find it rationally optimal to exploit them through deliberate defections. In general, sophisticated strategies have a problem. Because they are more difficult for other players to infer, their use increases the probability of miscommunication. But miscommunication is what causes repeated-game cooperative equilibria to unravel in the first place! The moral of this is that PDs, even repeated ones, are very difficult to escape from. Rational players do best trying to *avoid* situations that are PDs, rather than relying on cunning strategems for trying to get out of them.

Real, complex, social and political dramas are seldom straightforward instantiations of simple games such as PDs. Russell Hardin (1995) offers an analysis of two recent, very real (and very tragic) political cases, the Yugoslavian civil war of 1991-95, and the 1994 Rwandan genocide, as PDs that were nested inside *coordination games*. A coordination game occurs whenever the utility of two or more players is maximized by their doing the same thing, and where such correspondence is more important to them than *what*, in particular, they both do. A standard example arises with rules of the road: ‘All drive on the left’ and ‘All drive on the right’ are both outcomes that are NEs, and neither is more efficient than the other. In games of ‘pure’ coordination, it doesn't even help to use more selective equilibrium criteria. For example, suppose that we require our players to reason in accordance with Bayes's rule (see Section 3 above). In these circumstances, any strategy that is a best reply to any vector of mixed strategies available in NE is said to be *rationalizable*. That is, a player can find a set of systems of beliefs for the other players such that any history of the game along an equilibrium path is consistent with that set of systems. Pure coordination games are characterized by non-unique vectors of rationalizable strategies. In such

situations, players may try to predict equilibria by searching for *focal points*, that is, features of some strategies that they believe will be salient to other players, and that they believe other players will believe to be salient to them. Unfortunately, in many of the social and political games played by people (and some other animals), the biologically shallow properties by which people sort themselves into racial and ethnic groups serve highly efficiently as such features. Hardin's analysis of recent genocides relies on this fact.

According to Hardin, neither the Yugolslavian nor the Rwandan disasters were PDs to begin with. That is, in neither situation, on either side, did most people begin by preferring the destruction of the other to mutual cooperation. However, the deadly logic of coordination, deliberately abetted by self-serving politicians, dynamically *created* PDs. Some individual Serbs (Hutus) were encouraged to perceive their individual interests as best served through identification with Serbian (Hutu) group-interests. That is, they found that some of their circumstances, such as those involving competition for jobs, had the form of coordination games. They thus acted so as to create situations in which this was true for other Serbs (Hutus) as well. Eventually, once enough Serbs (Hutus) identified self-interest with group-interest, the identification became almost universally *correct*, because (1) the most important goal for each Serb (Hutu) was to do roughly what every other Serb (Hutu) would, and (2) the most distinctively *Serbian* thing to do, the doing of which permitted coordination, was to exclude Croats (Tutsi). That is, strategies involving such exclusionary behavior were selected as a result of having efficient focal points. This situation made it the case that an individual -- and individually threatened -- Croat's (Tutsi's) self-interest was best maximized by coordinating on assertive Croat (Tutsi) group-identity, which further increased pressures on Serbs (Hutus) to coordinate, and so on. Note that it is not an aspect of this analysis to suggest that Serbs or Hutus started things; the process could have been (even if it wasn't in fact) perfectly reciprocal. But the outcome is ghastly: Serbs and Croats (Hutus and Tutsis) seem progressively more threatening to each other as they rally together for self-defense, until both see it as imperative to preempt their rivals and strike before being struck. If Hardin is right -- and the point here is not to claim that he *is*, but rather to point out the worldly importance of determining which games agents are in fact playing -- then the mere presence of an external enforcer (NATO?) would not have changed the game, pace the Hobbesian analysis, since the enforcer could not have threatened either side with anything worse than what each feared from the other. What was needed was recalibration of evaluations of interests, which (arguably) happened in Yugoslavia when the Croatian army began to decisively win, at which point Bosnian Serbs decided that their self/group interests were best served by the arrival of NATO peacekeepers. The Rwandan conflict, meanwhile, drags on in the neighbouring country (the Congo) to which military and political developments have shifted it.

Of course, it is not the case that most repeated games lead to disasters. The biological basis of friendship in people and other animals is probably *partly* a function of the logic of repeated games. The importance of payoffs achievable through cooperation in future games leads those who expect to interact in them to be less selfish than temptation would suggest in present games. Furthermore, cultivating shared interests and sentiments provides networks of focal points around which coordination can be facilitated.

5. Commitment

In some games, players can improve their outcomes by taking actions that makes it impossible for them to take what would be her best actions in the corresponding simultaneous-move games. Such actions are referred to as *commitments,* and they can serve as alternatives to external enforcement in games which would otherwise settle on Pareto-inefficient equilibria.

Consider the following hypothetical example (which is *not* a PD). Suppose you own a piece of land adjacent to mine, and I'd like to buy it so as to expand my lot. Unfortunately, you don't want to sell at the price I'm willing to pay. If we move simultaneously -- you post a selling price and I independently give my agent an asking price -- there will be no sale. So I might try to change your incentives by playing an opening move in which I announce that I'll build a putrid-smelling sewage disposal plant on my land beside yours unless you sell, thereby lowering your price. I've now turned this into a sequential-move game. However, this move so far changes nothing. If you refuse to sell in the face of my threat, it is then not in my interest to carry it out, because in damaging you I also damage myself. Since you know this you should ignore my threat. My threat is *incredible,* a case of cheap talk.

However, I could make my threat credible by *committing* myself. I could sign a contract with some farmers promising to supply them with treated sewage (fertilizer) from my plant, but including an escape clause in the contract releasing me from my obligation only if I can double my lot size and so put it to some other use. Now my threat is credible: if you don't sell, I'm committed to building the sewage plant. Since you know this, you now have an incentive to sell me your land in order to escape its ruination.

This sort of case exposes one of many fundamental differences between the logic of non-parametric and parametric maximization. In parametric situations, an agent can never be made worse off by having more options. But where circumstances are non-parametric, one agent's strategy can be influenced in another's favour if options are visibly restricted. Cortez's burning of his boats (see Section 1) is, of course, an instance of this, one which serves to make the usual metaphor literal.

Another example will illustrate this, as well as the applicability of principles across game-types. Here we will build an imaginary situation that is not a PD -- since only one player has an incentive to defect -- but which is a social dilemma insofar as its NE in the absence of commitment is Pareto-inferior to an outcome that is achievable *with* a commitment device. Suppose that two of us wish to poach a rare antelope from a national park in order to sell the trophy. One of us must flush the animal down towards the second person, who waits in a blind to shoot it and load it onto a truck. You promise, of course, to share the proceeds with me. However, your promise is not credible. Once you've got the buck, you have no reason not to drive it away and pocket the full value from it. After all, I can't very well complain to the police without getting myself arrested too. But now suppose I add the following opening move to the game. Before our hunt, I rig out the truck with an alarm that can be turned off only by punching in a code. Only I know the code. If you try to drive off without me, the alarm will sound and we'll both get caught. You, knowing this, now have an incentive to wait for me. What is crucial to notice here is that you *prefer* that I rig up the alarm, since this makes your promise to give me my share credible. If I don't do this, leaving your promise *in*credible, we'll be unable to agree to try the crime in the first place, and both of us will lose our shot at the profit from selling the trophy. Thus, you benefit from my binding you.

We may now combine our analysis of PDs and commitment devices in discussion of the application that first made game theory famous outside of the academic community. The nuclear stand-off between the superpowers during the Cold War was exhaustively studied by the first generation of game theorists, many of whom worked for the US military. (See [Poundstone 1992] for historical details.) Both the USA and the USSR maintained the following policy. If one side launched a first strike, the other threatened to answer with a devastating counter-strike. This pair of reciprocal strategies, which by the late 1960s would effectively have meant blowing up the world, was known as ‘Mutually Assured Destruction’, or ‘MAD’. Game theorists objected that MAD was mad, because it set up a Prisoner's Dilemma as a result of the fact that the reciprocal threats were incredible. Suppose the USSR launches a first strike against the USA. At that point, the American President faces the following situation. His country is already destroyed. He doesn't bring it back to life by now blowing up the world, so he has no incentive to carry out his threat, which has now manifestly failed to achieve its point. Since the Russians know this, they should ignore the threat and strike first! Of course, the Americans are in exactly the same position. Each power will recognize this incentive on the part of the other, and so will anticipate an attack if they don't preempt it. What we should therefore expect, because it is the only NE of the game, is a race between the two powers to be the first to attack.

This game-theoretic analysis caused genuine consternation and fear on both sides during the Cold War, and produced some rather bizarre attempts at setting up strategic commitment devices. President Nixon, for example, had the CIA try to convince the Russians that he was insane, so that they'd believe that he'd launch a retaliatory strike even when it was no longer in his interest to do so. Similarly, the Soviet KGB leaked fabricated medical reports exaggerating Brezhnev's senility with the same end in mind. Ultimately, the Americans broke this deadly symmetry by using a ‘doomsday device’. They equipped a worldwide fleet of submarines with enough missiles to destroy the USSR, and arranged their communications technology in such a way that the President could not be *sure* to be able to reach the submarines and cancel their orders to attack if any Soviet missile crossed the radar ‘trigger line’. Of course, this strategy depended on making sure that the Russians were aware of the device. In Stanley Kubrick's classic film *Dr. Strangelove,* the world is destroyed by accident because the Russians build a doomsday machine *but then keep it a secret*! As a result, when a mad American colonel launches missiles at Russia on his own accord, and the American President tries to convince his Soviet counterpart that the attack was unintended, the Russian President sheepishly tells him about the secret doomsday machine. Now the two Presidents can do nothing but watch in dismay as the world is blown up -- due to a game-theoretic mistake.

Commitment can sometimes be secured through the value to a player of her own *reputation*. For example, a government tempted to negotiate with terrorists to secure the release of hostages on a particular occasion may commit to a ‘line in the sand’ strategy for the sake of maintaining a reputation for toughness intended to reduce terrorists' incentives to launch future attacks. A different sort of example is provided by Qantas Airlines of Australia. Qantas has never suffered an accident, and makes much of this in its advertising. This means that its planes probably *are* safer than average even if the initial advantage was merely a statistical artifact, because the value of its ability to claim a perfect record rises the longer it lasts, and so gives the airline continuous incentives to incur greater costs in safety assurance.

Certain conditions must hold if reputation effects are to underwrite commitment. First, the game must be repeated, with uncertainty as to which round is the last one. The repeated PD can be used to illustrate the importance of this principle. Cooperation can be the dominant strategy in a repeated PD because a player can gain more from his reputation for cooperation, through inducing expectations of cooperation in others, than he can gain through defection in a single round. However, if the players know in advance which round will be their last, this equilibrium unravels. In the last round reputation no longer has a value, and so both players will defect. In the second-last round, the players know they will defect in the last round, so reputation becomes worthless here too and they will again defect. This makes reputation worthless in the third-last round, and so on. The process iterates back to the first round, so no cooperation ever occurs. This point can be generalized to state the most basic condition on the possibility for using reputation effects as commitment devices: the value of the reputation must be greater to its cultivator than the value to him of sacrificing it in *any* particular round. Thus players may establish commitment by reducing the value of each round so that the temptation to defect in any round never gets high enough to make it rational. For example, parties to a contract may exchange their obligations in small increments to reduce incentives on both sides to renege. Thus builders in construction projects may be paid in weekly or monthly installments. Similarly, the International Monetary Fund often dispenses loans to governments in small tranches, thereby reducing governments' incentives to violate loan conditions once the money is in hand; and governments may actually prefer such arrangements in order to remove domestic political pressure for non-compliant use.

6. Evolutionary Game Theory

Gintis (2000) has recently felt justified in stating baldly that "game theory is a universal language for the unification of the behavioral sciences." This may seem an extraordinary thing to say, but it is entirely plausible. Binmore (1998) has modeled social history as a series of convergences on increasingly efficient equilibria in commonly encountered transaction games, interrupted by episodes in which some people try to shift to new equilibria by moving off stable equilibrium paths, resulting in periodic catastrophes. (Stalin, for example, tried to shift his society to a set of equilibria in which people cared more about the future industrial power and equitability of their society than they cared about their own lives. He was not successful; however, his efforts certainly created a situation in which, for a few decades, many Soviet people attached far less importance to *other people's* lives than usual.) Furthermore, applications of game theory to behavioral topics extend well beyond the political arena.

In 1969, for example, the philosopher David Lewis (1969) published *Convention*, in which the conceptual framework of game-theory was applied to one of the fundamental issues of twentieth-century epistemology, the nature and extent of conventions governing semantics and their relationship to the justification of propositional beliefs. This book stands as one of the classics of analytic philosophy, and its stock is presently rising still further as we become more aware of the significance of the trail it blazed. The basic insight can be captured using a simple example. The word ‘chicken’ denotes chickens and ‘ostrich’ denotes ostriches. We would not be better or worse off if ‘chicken’ denoted ostriches and ‘ostrich’ denoted chickens; however, we *would* be worse off if half of us used the pair of words the first way and half the second, or if all of us randomized between them to refer to flightless birds generally.

This insight, of course, well preceded Lewis; but what he recognized is that this situation has the logical form of a coordination game. Thus, while particular conventions may be arbitrary, the interactive structures that stabilize and maintain them are not. Furthermore, the equilibria involved in coordinating on noun-meanings appear to have an arbitrary element only because we cannot Pareto-rank them; but Millikan (1984) shows implicitly that in this respect they are atypical of linguistic coordinations. In general, the various NE in coordination games can very often be ranked. Ross & LaCasse (1995) present the following example. In a city, drivers must coordinate on one of two NE with respect to their behaviour at traffic lights. Either all must rush yellows and pause on shifts to green, or slow down on yellows and jump forward on shifts to green. Both patterns are NE, in that once a community has coordinated on one of them no individual has an incentive to deviate: those who slow down on yellows while others are rushing them will get rear-ended, while those who rush yellows in the other equilibrium will risk collision with those who jump forward quickly on greens. Therefore, once a city's traffic pattern settles on one of these equilibria it will tend to stay there. However, the two states are not Pareto-indifferent, since the second NE allows more cars to turn left on each cycle (in a right-hand-drive jurisdiction), which reduces the extent of bottlenecks and allows all drivers to expect greater efficiency in getting about. Conventions on standards of evidence and rationality are likely to be of this character. While various arrangements might be NE in the social game of science, as followers of Thomas Kuhn like to remind us, it is highly improbable that all of these lie on a single Pareto-indifference curve. These themes, strongly represented in contemporary epistemology, philosophy of science and philosophy of language, are all bequests of game theory by way (at least indirectly) of Lewis. (The reader can find a broad sample of applications, and references to the large literature, in Nozick (1998).) However, Lewis restricted his attention to static game theory, in which agents *choose* strategies given exogenously fixed utility-functions. As a result of this restriction, his account is able to show us why conventions are important and stable, but it invites a difficult and perhaps ultimately fruitless quest for a general theory of rationality. This is because, as we saw in Section 3 above, in coordination (and other) games with multiple NE, what counts as a solution is highly sensitive to conjectures made by players about one another's beliefs and computational ability. This has excited a good deal of attention, especially from philosophers, on the implications of many subtle variations in the norms of strategic rationality. However, if game theory is to explain actual, natural behavior and its history in the way suggested by Gintis (2000) above, then we need some account of what is attractive about equilibria in games even when no analysts or rational calculators are around to identify them. To make reference again to Lewis's topic, when human language developed there was no external referee to care about and arrange for Pareto-efficiency. In order to understand Gintis's optimism about the reach of game theory, we must therefore extend our attention to *evolutionary* games.

Game theory has been fruitfully applied in evolutionary biology, where species and/or genes are treated as players, since pioneering work by Maynard Smith (1982) and his collaborators. Evolutionary (or *dynamic*) game theory now constitutes a significant new mathematical extension applicable to many settings apart from the biological. Thus Skyrms (1996) uses evolutionary game theory to try to answer questions Lewis could not even ask, about the conditions under which language, concepts of justice, the notion of private property, and other non-designed, general phenomena of interest to philosophers would be likely to arise. What is novel about evolutionary game theory is that moves are not chosen by rational agents. Instead, agents are typically hard-wired with particular strategies, and success for a strategy is defined in terms of the number of copies that a strategy will leave of itself to play in the games of

succeeding generations. The strategies themselves are therefore the players, and the games they play are dynamic rather than static.

The discussion here will closely follow Skyrms's. We begin by introducing *the replicator dynamics*. Consider first how natural selection works to change lineages of animals, modifying, creating and destroying species. The basic mechanism is *differential reproduction*. Any animal with *heritable* features that increase its *expected number of offspring* in a given environment will tend to leave more offspring than others so long as the environment remains relatively stable. These offspring will be more likely to inherit the features in question. Therefore, the proportion of these features in the population will gradually increase as generations pass. Some of these features may *go to fixation*, that is, eventually take over the entire population (until the environment changes).

How does game theory enter into this? Often, one of the most important aspects of an organism's environment will be the behavioural tendencies of other organisms. We can think of each lineage as 'trying' to maximize its reproductive fitness (= expected number of grandchildren) through finding strategies that are optimal given the strategies of other lineages. So evolutionary theory is another domain of application for non-parametric analysis.

In dynamic game theory, we no longer think of individuals as choosing strategies as they move from one game to another. This is because our interests are different. We're now concerned less with finding the equilibria of single games than with discovering which equilibria are stable, and how they will change over time. So we now model *the strategies themselves* as playing against each other. One strategy is 'better' than another if it is likely to leave more copies of itself in the next generation, when the game will be played again. We study the changes in distribution of strategies in the population as the sequence of games unfolds.

For dynamic game theory, we introduce a new equilibrium concept, due to Maynard Smith (1982). A set of strategies, in some particular proportion (e.g., 1/3:2/3, 1/2:1/2, 1/9:8/9, 1/3:1/3:1/6:1/6 -- always summing to 1) is at an *ESS* (Evolutionary Stable Strategy) equilibrium just in case (1) no individual playing one strategy could improve its reproductive fitness by switching to one of the other strategies in the proportion, and (2) no mutant playing a different strategy altogether could establish itself ('invade') in the population.

The principles of evolutionary game theory are best explained through examples. Skyrms begins by investigating the conditions under which a sense of justice -- understood as a disposition to view equal divisions of resources as fair unless efficiency considerations suggest otherwise in special cases -- might arise. He asks us to consider a population in which individuals regularly meet each other and must bargain over resources. Begin with three types of individuals:

a. *Fairmen* always demand exactly half the resource.
b. *Greedies* always demand more than half the resource. When a greedy encounters another greedy, they waste the resource in fighting over it.

c. *Modests* always demand less than half the resource. When a modest encounters another modest, they take less than all of the available resource and waste some.

Each *single* encounter where the total demands sum to 100% is a NE of that individual game. Similarly, there can be many dynamic equilibria. Suppose that Greedies demand 2/3 of the resource and Modests demand 1/3. Then the following two proportions are ESS's:

i. Half the population is greedy and half is modest. We can calculate the average payoff here. Modest gets 1/3 of the resource in every encounter. Greedy gets 2/3 when she meets Modest, but nothing when she meets another Greedy. So her average payoff is also 1/3. This is an ESS because Fairman can't invade. When Fairman meets Modest he gets 1/2. But when Fairman meets Greedy he gets nothing. So his average payoff is only 1/4. No Modest has an incentive to change strategies, and neither does any Greedy. A mutant Fairman arising in the population would do worst of all, and so selection will not encourage the propagation of any such mutants.
ii. All players are Fairmen. Everyone always gets half the resource, and no one can do better by switching to another strategy. Greedies entering this population encounter Fairmen and get an average payoff of 0. Modests get 1/3 as before, but this is less than Fairman's payoff of 1/2.

Notice that equilibrium (i) is inefficient, since the average payoff across the whole population is smaller. However, just as inefficient outcomes can be NE of static games, so they can be ESS's of dynamic ones.

We refer to equilibria in which more than one strategy occurs as *polymorphisms*. In general, in Skyrms's game, any polymorphism in which Greedy demands x and Modest demands 1-x is an ESS. The question that interests the student of justice concerns the relative likelihood with which these different equilibria arise.

This depends entirely on the proportions of strategies in the original population state. If the population begins with more than one Fairman, then there is some probability that Fairmen will encounter each other, and get the highest possible average payoff. Modests by themselves do not inhibit the spread of Fairmen; only Greedies do. But Greedies themselves depend on having Modests around in order to be viable. So the more Fairmen there are in the population relative to *pairs* of Greedies and Modests, the better Fairmen do on average. This implies a threshold effect. If the proportion of Fairmen drops below 33%, then the tendency will be for them to fall to extinction because they don't meet each other often enough. If the population of Fairmen rises above 33%, then the tendency will be for them to rise to fixation because their extra gains when they meet each other compensates for their losses when they meet Greedies. You can see this by noticing that when each strategy is used by 33% of the population, all have an expected average payoff of 1/3. Therefore, any rise above this threshold on the part of Fairmen will tend to push them towards fixation.

This result shows that and how, given certain relatively general conditions, justice as we have defined it *can* arise dynamically. The news for the fans of justice gets more cheerful still if we introduce *correlated play*.

The model we just considered assumes that strategies are not *correlated*, that is, that the probability with which every strategy meets every other strategy is a simple function of their relative frequencies in the population. We now examine what happens in our dynamic resource-division game when we introduce correlation. Suppose that Fairmen have a slight ability to distinguish and seek out other Fairmen as interaction partners. In that case, Fairmen on average do better, and this must have the effect of lowering their threshold for going to fixation.

A dynamic-game modeler studies the effects of correlation and other parametric constraints by means of running large computer simulations in which the strategies compete with one another, round after round, in the virtual environment. The starting proportions of strategies, and any chosen degree of correlation, can simply be set in the programme. One can then watch its dynamics unfold over time, and measure the proportion of time it stays in any one equilibrium. These proportions are represented by the relative sizes of the *basins of attraction* for different possible equilibria. Equilibria are attractor points in a dynamic space; a basin of attraction for each such point is then the set of points in the space from which the population will converge to the equilibrium in question.

In introducing correlation into his model, Skyrms first sets the degree of correlation at a very small .1. This causes the basin of attraction for equilibrium (i) to shrink by half. When the degree of correlation is set to .2, the polymorphic basin reduces to the point at which the population starts in the polymorphism. Thus very small increases in correlation produce large proportionate increases in the stability of the equilibrium where everyone plays Fairman. A small amount of correlation is a reasonable assumption in most populations, given that neighbours tend to interact with one another and to mimic one another (either genetically or because of tendencies to deliberately copy each other), and because genetically similar animals are more likely to live in common environments. Thus if justice can arise at all it will tend to be dominant and stable.

Much of political philosophy consists in attempts to produce deductive normative arguments intended to convince an unjust agent that she has reasons to act justly. Skyrms's analysis suggests a quite different approach. Fairman will do best of all in the dynamic game if he takes active steps to preserve correlation. Therefore, there is evolutionary pressure for both *moral approval of justice* and *just institutions* to arise. Most people may think that 50-50 splits are ‘fair’, and worth maintaining by moral and institutional reward and sanction, *because* we are the products of a dynamic game that promoted our tendency to think this way.

The topic that has received most attention from evolutionary game theorists is *altruism*, defined as any behaviour by an organism that decreases its own expected fitness in a single interaction but increases that of the other interactor. It is common in nature. How can it arise, however, given Darwinian competition?

Skyrms studies this question using the dynamic Prisoner's Dilemma as his example. This is simply a series of PD games played in a population, some of whose members are defectors and some of whom are cooperators. Payoffs, as always in dynamic games, are measured in terms of expected numbers of copies of each strategy in future generations.

Let **U**(*A*) be the average fitness of strategy *A* in the population. Let **U** be the average fitness of the whole population. Then the proportion of strategy *A* in the next generation is just the ratio **U**(*A*)/**U**. So if *A* has greater fitness than the population average *A* increases. If *A* has lower fitness than the population average then *A* decreases.

In the dynamic PD where interaction is random (i.e., there's no correlation), defectors do better than the population average as long as there are cooperators around. This follows from the fact that, as we saw in Section 2.4, defection is always the dominant strategy in a single game. 100% defection is therefore the ESS in the dynamic game without correlation, corresponding to the NE in the one-shot static PD.

However, introducing the possibility of correlation radically changes the picture. We now need to compute the average fitness of a strategy *given its probability of meeting each other possible strategy*. In the dynamic PD, cooperators whose probability of meeting other cooperators is high do better than defectors whose probability of meeting other defectors is high. Correlation thus favours cooperation.

In order to be able to say something more precise about this relationship between correlation and cooperation (and in order to be able to relate evolutionary game theory to issues in decision theory, a matter falling outside the scope of this article), Skyrms introduces a new technical concept. He calls a strategy *adaptively ratifiable* if there is a region around its fixation point in the dynamic space such that from anywhere within that region it will go to fixation. In the dynamic PD, both defection and cooperation are adaptively ratifiable. The relative sizes of basins of attraction are highly sensitive to the particular mechanisms by which correlation is achieved. To illustrate this point, Skyrms builds several examples.

One of Skyrms's models introduces correlation by means of a *filter* on pairing for interaction. Suppose that in round 1 of a dynamic PD individuals inspect each other and interact, or not, depending on what they find. In the second and subsequent rounds, all individuals who didn't pair in round 1 are randomly paired. In this game, the basin of attraction for defection is large *unless* there is a high proportion of cooperators in round one. In this case, defectors fail to pair in round 1, then get paired mostly with each other in round 2 and drive each other to extinction. A model which is more interesting, because its mechanism is less artificial, does not allow individuals to choose their partners, but requires them to interact with those closest to them. Because of genetic relatedness (or cultural learning by copying) individuals are more likely to resemble their neighbours than not. If this (finite) population is arrayed along one dimension (i.e., along a line), and both cooperators and defectors are introduced into positions along it at random, then we get the following dynamics. Isolated cooperators have lower expected fitness than the surrounding defectors and are driven locally to extinction. Members of groups of two cooperators have a 50% probability of interacting with each other, and a 50% probability of each interacting with a defector. As a result, their average expected fitness remains smaller than that of their neighbouring defectors, and they too face probable extinction. Groups of three cooperators form an unstable point from which both extinction and expansion are equally likely. However, in groups of four or more cooperators at least one encounter of a cooperator with a cooperator sufficient to at least replace the original group is guaranteed. Under this circumstance, the cooperators as a group do better than the surrounding defectors and increase at their expense. Eventually cooperators go *almost* to fixation -- but nor quite. Single

defectors on the periphery of the population prey on the cooperators at the ends and survive as little 'criminal communities'. We thus see that altruism can not only be maintained by the dynamics of evolutionary games, but, with correlation, can even spread and colonize originally non-altruistic populations.

Darwinian dynamics thus offers qualified good news for cooperation. Notice, however, that this holds only so long as individuals are stuck with their natural or cultural programming and can't re-evaluate their utilities for themselves. If our agents get too smart and flexible, they may notice that they're in PDs and would each be best off defecting. In that case, they'll eventually drive themselves to extinction - unless they develop stable, and effective, moral norms that work to reinforce cooperation. But, of course, these are just what we would expect to evolve in populations of animals whose average fitness levels are closely linked to their capacities for successful social cooperation. Even given this, these populations will go extinct unless they care about future generations for some reason. But there's no rational reason as to why agents *should* care about future generations if each new generation wholly replaces the preceding one at each change of cohorts. For this reason, economists use 'overlapping generations' models when modeling distribution games. Individuals in generation 1 who will last until generation 5 save resources for the generation 3 individuals with whom they'll want to cooperate; and by generation 3 the new individuals care about generation 6; and so on.

An enormous range of further applications of both static and dynamic game theory have been developed, but we have perhaps now provided enough to convince the reader of the tremendous utility of this analytical tool. The reader whose appetite for more has been thoroughly aroused should find that she now has sufficient grasp of fundamentals to be able to work through the large literature, of which some highlights are listed below.

Bibliography

Annotations

In the following section, books which no philosopher seriously interested in game theory can afford to miss are marked with (**).

Game theory has countless applications, of which this article has been able to suggest only a few. Readers in search of more, but not wishing to immerse themselves in mathematics, can find a number of good sources. Dixit and Nalebuff (1991) is especially strong on political and social examples. McMillan (1991) emphasizes business applications. The great historical breakthrough is von Neumann and Morgenstern (1947), which those with scholarly interest in game theory should read with classic papers of John Nash (1950a, 1950b, 1951). For a contemporary mathematical treatment that is unusually philosophically sophisticated, Binmore (1992) (**) is in a class by itself. The second half of Kreps (1990) (**) is the best available starting point for a tour of the philosophical worries surrounding equilibrium selection for non-behaviorists. Koons (1992) takes these issues further. Fudenberg and Tirole (1991) is the most thorough

and complete mathematical text available. Gintis (2000) (**) has provided a new text crammed with terrific problem exercises, which is also unique in that it treats evolutionary game theory as providing the foundational basis for game theory *in general*. This likely represents the wave of the future. Recent developments in fundamental theory are well represented in Binmore, Kirman and Tani (1993).

The philosophical foundations of the basic game-theoretic concepts as economists understand them are presented in LaCasse and Ross (1994). Ross and LaCasse (1995) outline the relationships between games and the axiomatic assumptions of microeconomics and macroeconomics. Philosophical puzzles at this foundational level are critically discussed in Bicchieri (1993) (**). Lewis (1969) (**) puts game-theoretic equilibrium concepts to wider application in philosophy, a program that is carried a good deal further in Skyrms (1996) (**). (See also Nozick [1998].) Gauthier (1986) launches a literature not surveyed in this article, in which the possibility of game-theoretic foundations for contractarian ethics is investigated. This work is critically surveyed in Vallentyne (1991), and extended into a dynamic setting in Danielson (1992). Binmore (1994, 1998) (**), however, effectively demolishes this project. Philosophers will also find Hollis (1998) to be of interest.

Hardin (1995) is one of many examples of the application of game theory to problems in applied political theory. Baird, Gertner and Picker (1994) review uses of game theory in legal theory and jurisprudence. Mueller (1997) surveys applications in political economy. Ghemawat (1997) does the same in business strategy. Poundstone (1992) provides a lively history of the Prisoner's Dilemma and its use by Cold War strategists. Durlauf and Young (2001) is a good collection on applications to social structures and social change.

Evolutionary game theory owes its explicit genesis to Maynard Smith (1982) (**). For a text that integrates game theory directly with biology, see Sigmund (1993). The most exciting applications of evolutionary game theory to a range of philosophical issues, on which this article has drawn heavily, is Skyrms (1996) (**). These issues and others are critically discussed from various angles in Danielson (1998). Mathematical foundations for dynamic games are presented in Weibull (1995), and pursued further in Samuelson (1997) and Fudenberg and Levine (1998). As noted above, Gintis (2000) (**) now provides an introductory textbook that takes evolutionary modeling to be foundational to all of game theory. Many philosophers will also be interested in Binmore (1994, 1998) (**), which shows that application of game-theoretic analysis can underwrite a loosely Rawlsian theory of justice that does not require recourse to Kantian presuppositions about what rational agents would desire behind a veil of ignorance concerning their identities and social roles. (In addition, Binmore offers excusions into a vast range of other issues both central and peripheral to both the foundations and the frontiers of game theory; these books are a tour de force.) And almost everyone will be interested in Frank (1988) (**), where evolutionary game theory is used to illuminate basic features of human nature and emotion.

Acknowledgments

I would like to thank James Joyce and Edward Zalta for their comments on the original version and on the first draft of the revised version of this entry. I would also like to thank Anthony Boting, for noticing that my solution to one of the examples rested on equivocating between relative-frequency and objective-chance interpretations of probability. Finally, thanks go to Colin Allen for all his technical support behind the scenes (in the effort to deal with bandwidth problems to South Africa) prior to publication of the revised version of this entry.

Prisoner's Dilemma

Tanya and Cinque have been arrested for robbing the Hibernia Savings Bank and placed in separate isolation cells. Both care much more about their personal freedom than about the welfare of their accomplice. A clever prosecutor makes the following offer to each. "You may choose to confess or remain silent. If you confess and your accomplice remains silent I will drop all charges against you and use your testimony to ensure that your accomplice does serious time. Likewise, if your accomplice confesses while you remain silent, they will go free while you do the time. If you both confess I get two convictions, but I'll see to it that you both get early parole. If you both remain silent, I'll have to settle for token sentences on firearms possession charges. If you wish to confess, you must leave a note with the jailer before my return tomorrow morning."

The "dilemma" faced by the prisoners here is that, whatever the other does, each is better off confessing than remaining silent. But the outcome obtained when both confess is worse for each than the outcome they would have obtained had both remained silent. A common view is that the puzzle illustrates a conflict between individual and group rationality. A group whose members pursue rational self-interest may all end up worse off than a group whose members act contrary to rational self-interest. More generally, if the payoffs are not assumed to represent self-interest, a group whose members rationally pursue any goals may all meet less success than if they had not rationally pursued their goals individually. Puzzles with this structure were devised and discussed by Merrill Flood and Melvin Dresher in 1950, as part of the Rand Corporation's investigations into game theory (which Rand pursued because of possible applications to global nuclear strategy). The title "prisoner's dilemma" and the version with prison sentences as payoffs are due to Albert Tucker, who wanted to make Flood and Dresher's ideas more accessible to an audience of Stanford psychologists. Although Flood and Dresher didn't themselves rush to publicize their ideas in external journal articles, the puzzle attracted widespread attention in a variety of disciplines. Christian Donninger reports that "more than a thousand articles" about it were published in the sixties and seventies. A bibliography (Axelrod and D'Ambrosio) of writings between 1988 and 1994 that pertain to Robert Axelrod's research on the subject lists 209 entries. Since then the flow has shown no signs of abating.

The sections below provide a variety of more precise characterizations of the prisoner's dilemma, beginning with the narrowest. ‘Prisoner's dilemma’ is abbreviated as ‘PD’. Future editions of the entry will also survey some applications in philosophy, and attempts to "solve" the PD by showing that remaining silent is individually rational after all.

Symmetric 2x2 PD With Ordinal Payoffs

In its simplest form the PD is a game described by the payoff matrix:

	C	**D**
C	R,R	S,T
D	T,S	P,P

satisfying the following chain of inequalities:

PD1) T>R>P>S

There are two players, Row and Column. Each has two possible moves, "cooperate" or "defect," corresponding, respectively, to the options of remaining silent or confessing in the illustrative anecdote above. For each possible pair of moves, the payoffs to Row and Column (in that order) are listed in the appropriate cell. R is the "reward" payoff that each player receives if both cooperate. P is the "punishment" that each receives if both defect. T is the "temptation" that each receives if he alone defects and S is the "sucker" payoff that he receives if he alone cooperates. We assume here that the game is symmetric, i.e., that the reward, punishment, temptation or sucker payoff is the same for each player, and payoffs have only ordinal significance, i.e., they indicate whether one payoff is better than another, but tell us nothing about how much better. It is now easy to see that we have the structure of a dilemma like the one in the story. Suppose Column cooperates. Then Row gets R for cooperating and T for defecting, and so is better off defecting. Suppose Column defects. Then Row gets S for cooperating and P for defecting, and so is again better off defecting. The move **D** for Row is said to *strictly dominate* the move **C**: whatever his opponent

does, he is better off choosing **D** than **C**. By symmetry **D** also strictly dominates **C** for Column. Thus two "rational" players will defect and receive a payoff of P, while two "irrational" players can cooperate and receive greater payoff R. In standard treatments, game theory assumes rationality and common knowledge. Each player is rational, knows the other is rational, knows that the other knows he is rational, etc. Each player also knows how the other values the outcomes. But since **D** strictly dominates C for both players, the argument for dilemma here requires only that each player knows his own payoffs. (The argument remains valid, of course, under the stronger standard assumptions.) It is also worth noting that the outcome (**D**,**D**) of both players defecting is the game's only strong nash equilibrium, i.e., it is the only outcome from which each player could only do worse by unilaterally changing its move. Flood and Dresher's interest in their dilemma seems to have stemmed from their view that it provided a counterexample to the claim that the nash equilibria of a game constitute its natural "solutions".

If there can be "ties" in rankings of the payoffs, condition PD1 can be weakened without destroying the nature of the dilemma. For suppose that one of the following conditions obtain:

PD2) $T>R>P\geq S$, or
$T\geq R>P>S$

Then, for each player, although **D** does not strictly dominate **C**, it still *weakly dominates* in the sense that each player always does at least as well, and sometimes better, by playing **C**. Under these conditions it still seems rational to play **D**, which again results in the payoff that neither player prefers. Let us call a game that meets PD2 a *weak PD*. Note that in a weak PD that does not satisfy PD1 mutual defection is no longer a nash equilibrium in the strong sense defined above. It is still, however, the only nash equilibrium in the weaker sense, that neither player can improve its position by unilaterally changing its move. Again, one might suppose that if there is a unique nash equilibrium of this weaker variety, rational self-interested players would reach it.

Asymmetry

Without assuming symmetry, the PD can be represented by using subscripts r and c for the payoffs to Row and Column.

	C	**D**
C	R_r,R_c	S_r,T_c
D	T_r,S_c	P_r,P_c

If we assume that the payoffs are ordered as before for each player, i.e., that $T_i>R_i>P_i>S_i$ when i=r,c, then, as before, **D** is the strictly dominant move for both players, but the outcome (**D**,**D**) of both players making this move is worse for each than (**C**,**C**). The force of the dilemma can now also be felt under weaker conditions, however. Consider the following three pairs of inequalities:

PD3) a. $T_r > R_r$ and $P_r > S_r$

b. $T_c > R_c$ and $P_c > S_c$

c. $R_r > P_r$ and $R_c > P_c$

If these conditions all obtain the argument for dilemma goes through as before. Defection strictly dominates cooperation for each player, and (**C**,**C**) is strictly preferred by each to (**D**,**D**). If one of the two > signs in each of the conditions a - c is replaced by a weak inequality sign $\geq$ we have a weak PD. **D** weakly dominates **C** for each player (i.e., **D** is as good as **C** in all cases and better in some) and (**C**,**C**) weakly better than (**D**,**D**) (i.e., it is at least as good for both players and better for one). Since none of the clauses requires comparisons between r's payoffs and c's, we need not assume that > has any "interpersonal" significance.

Now suppose we drop the first inequality of either a or b (but not both). A game that meets the resulting conditions might be termed a *common knowledge PD*. As long as each player knows that the other is rational and each knows the other's ordering of payoffs, we still feel the force of the dilemma. For suppose b holds. Then **D** is the dominant move for Row. Column, knowing that Row is rational, knows that Row will defect, and so, by the remaining inequality in b, will defect himself. Similarly, if b holds Column will defect, and Row, realizing this, will defect herself. By c, the resulting (**D**,**D**) is again worse for both than (**C**,**C**).

Multiple Moves

Speaking generally, one might say that a PD is a game in which a "cooperative" outcome obtainable only when every player violates rational self-interest is unanimously preferred to the "selfish" outcome obtained when every player adheres to rational self-interest. We can characterize the selfish outcome either as the result of each player pursuing its dominant (strongly dominant) strategy, or as the unique weak (strong) nash equilibrium. In a two move game the two characterizations come to the same thing **--** a dominant move pair is a unique equilibrium and a unique equilibrium is a dominant move pair. As the payoff matrix below shows, however, the two notions diverge in a game with more than two moves.

	C	**D**	**N**
C	R,R	S,T	T,S
D	T,S	P,P	R,S
N	S,T	S,R	S,S

Here each player can choose "cooperate", "defect" or "neither" and the payoffs are ordered as before. Defection is no longer dominant, because each player is better off choosing **C** than **D** when the other chooses N. Nevertheless (**D**,**D**) is still the unique equilibrium. Let us label a game like this in which the selfish outcome is the unique equilibrium an *equilibrium PD*, and one in which the selfish outcome is a pair of dominant moves a *dominance PD*. As will be seen below, attempts to "solve" the PD by allowing

conditional strategies can create multiple-move games that are themselves equilibrium PDs.

Multiple Players

Most of those who maintain that the PD illustrates something important about morality seem to believe that the basic structure of the game is reflected in situations that larger groups, perhaps entire societies, face. The most obvious generalization from the two-player to the many-player game would pay each player R if all cooperate, P if all defect, and, if some cooperate and some defect, it would pay the cooperators S and the defectors T. But it is unlikely that we face many situations of this structure.

A common view is that a multi-player PD structure is reflected in what Garret Hardin popularized as "the tragedy of the commons." Each member of a group of neighboring farmers prefers to allow his cow to graze on the commons, rather than keeping it on his own inadequate land, but the commons will be rendered unsuitable for grazing if it is used by more than some threshold number use it. More generally, there is some social benefit B that each member can achieve if sufficiently many pay a cost C. We might represent the payoff matrix as follows:

	***n* or fewer choose C**	**more than *n* choose C**
C	C	C+B
D	0	B

The cost C is assumed to be a negative number. The "temptation" here is to get the benefit without the cost, the reward is the benefit with the cost, the punishment is to get neither and the sucker payoff is to pay the cost without realizing the benefit. So the payoffs are ordered B > (B+C) > 0 > C. As in the two-player game, it appears that **D** weakly dominates **C** for all players, and so rational players would choose **D** and achieve 0, while preferring that everyone would choose **C** and obtain C+B.

Unlike the more straightforward generalization, this matrix does reflect common social choices -- between depleting and conserving a scarce resource, between using polluting and non-polluting means of manufacture or disposal, and between participating and not participating in a group effort towards some common goal. When *n* is small, it represents a version of what has been called the "volunteer dilemma". A group needs a few volunteers, but each member is better off if others volunteer. (Notice, however, that in a true volunteer dilemma, where only one volunteer is needed, *n* is zero and the top left outcome is impossible. Under these conditions D no longer dominates **C** and the game loses its PD flavor.) A particularly vexing manifestation of this game occurs when a vaccination known to have serious risks is needed to prevent the outbreak of a fatal disease. If enough of her neighbors get the vaccine, each person may be protected without assuming the risks.

The tragedy of the commons game diagramed above has a somewhat different character than the two-player PD. First, even if each player's moves are entirely independent of the others, the alternatives represented by the columns in the commons matrix above are no longer independent of the alternatives represented by the

rows. My choosing **C** necessarily increases the chances that more than *n* people will choose **C**. To ensure independence we should really redraw the matrix as follows:

	fewer than *n* others choose C	***n* others choose C**	**more than *n* others choose C**
C	C	C+B	C+B
D	0	0	B

But now we see that move **D** does *not* dominate **C**. When we are at the threshold of adequate cooperation, I am better off cooperating. Provided that *n* is large, however, it would seem that this effect could be ignored and we could assume, for practical purposes, that the payoff matrix is like the previous one.

Similarly, whereas we saw in the original PD that mutual defection was the only nash equilibrium, this game has two equilibria. One is universal defection, since any player unilaterally departing from that outcome will move from payoff 0 to C. But a second is the state of *minimally effective* cooperation, where the number of cooperators just exceeds the threshold n. A defector who unilaterally departs from that outcome will move from B to B+C and a cooperator who unilaterally departs will move from B+C to 0. This might suggest that the tragedy of the commons is less tragic than the PD, but in real life situations, it would seem unlikely that the participants would know when they are at the equilibrium point of minimally effective cooperation.

Furthermore, in the ordinary PD, universal cooperation is a pareto-optimal outcome, i.e., there is no outcome in which each player is at least as well off and some are better off. But in the commons game the only pareto optimal outcomes are those of minimally effective cooperation. Whether universal cooperation is nevertheless desirable may depend on the nature of the choices involved. In the medical example it may seem best to vaccinate everyone. In the agricultural example, however it seems foolish to stipulate that nobody use the commons. Someone who avoids vaccination in the former case is seen as a "free rider". An underused commons in the latter seems to exemplify "surplus cooperation."

The two-person version of the tragedy of the commons game (with threshold of one) produces a matrix presenting little or no dilemma.

	C	**D**
C	B+C,B+C	C,0
D	0,C	0,0

This game captures David Hume's example of a boat with one oarsman on the port side and another on the starboard. Mutual cooperation is identical to minimally effective cooperation and therefore is both an equilibrium outcome and a pareto optimal outcome.

The above representations of the tragedy of the commons make the simplifying assumptions that the costs and benefits to each player are the same, and that these costs and benefits are independent of the number of players who cooperate. A somewhat more general account would replace C and B by functions C(i,j) and B(i,j) representing the cost of cooperation to player i when he is one of exactly j players who cooperate and the benefit to player i when exactly j players cooperate. For each player i, we suppose that there is some threshold t_i such that B(i,j) is not defined unless $j>t_i$. We may assume additional cooperation never reduces the benefit i gets from general cooperation, i.e., $B(i,j+1) \geq B(i,j)$ and that additional defection never reduces the cost i bears in cooperating, i.e, $C(i,j+1) \geq C(i,j)$. Now suppose that, for all players i, B(i,j)>(B(i,j+1)+C(i,j+1)) when j is greater than the threshold for i but less than the total number of players, and 0>C(i,j) when j is less than the threshold for i. Suppose additionally that, for all i and all j greater than the threshold for i, B(i,j)+C(i,j)>0. We then have a tragedy of the commons game, which (if we ignore the outcome of minimally effective cooperation) presents the familiar dilemma: defection is individually rational, but general cooperation benefits everyone.

Phillip Pettit has pointed out that examples that might be represented as many-player PD's come in two flavors. The examples discussed above might be classified as free-rider problems. My temptation is to enjoy some benefits brought about by burdens shouldered by others. The other flavor is what Pettit calls "foul dealer" problems. My temptation is to benefit myself by hurting others. Suppose, for example, that a group of people are applying for a single job, for which they are equally qualified. If all fill out their applications honestly, they all have an equal chance of being hired. If one lies, however, he can ensure that he is hired while, let us say, incurring a small risk of being exposed later. If everyone lies, they again have an equal chance for the job, but now they all incur the risk of exposure. Thus a lone liar, by reducing the others' chances of employment from slim to none, raises his own chances from slim to sure. As Pettit points out, when the minimally effective level of cooperation is the same as the size of the population, there is no opportunity for free-riding (everyone's cooperation is needed), and so the PD must be of the foul-dealing variety. But (Pettit's contrary claim notwithstanding) not all foul-dealing PDs seem to have this feature. Suppose, for example, that two applicants in the story above will be hired. Then everyone gets the benefit (a chance of employment without risk of exposure) unless two or more players lie. Nevertheless, the liars seem to be foul dealers rather than free riders. A better characterization of the foul-dealing dilemma might be that every defection from a generally cooperative state strictly reduces the payoffs to the cooperators, i.e., for every player i and every j greater than i's threshold, either B(i,j+1)>B(i,j) or C(i,j+1)>C(i,j). A free-rider's defection benefits himself but does not, by itself, hurt the cooperators. A foul-dealer's defection benefits himself and hurts the cooperators.

The game labeled a many-person PD in Schelling, Molander 1992 and elsewhere requires that the payoff to each co-operator and defector increases strictly with the number of cooperators and that the sum of the payoffs to all parties increases with the number of cooperators (so that one party's switching from defection to cooperation always raises the sum). Neither of these conditions is met by the formulation and the examples discussed above. They may, however, hold "locally," i.e., for j close to the threshold of minimally effective cooperation, it may be reasonable to assume B(i,j+1)+C(i,j+1)>B(i,j)+C(i,j), B(i,j+1)>B(i,j) and B(1,j+1)+C(1,j+1)+...+B(j+1,j+1)+C(j+1,j+1)+B(j+2,j+1))+...+B(n,j+1) > B(1,j)+C(1,j)+...+B(j,j)+C(j,j)+B(j+1,j)+...+B(n,j).

Single Person Interpretation

The PD is usually thought to illustrate conflict between individual and collective rationally, but the multiple player form (or something very similar) has also been interpreted as demonstrating problems within standard conceptions of individual rationality. This interpretation, elucidated in Quinn, derives from an example of Parfit's. A medical device enables electric current to be applied to a patient's body in increments so tiny that there is no perceivable difference between adjacent settings. You are attached to the device and given the following choice every day for ten years: advance the device one setting and collect a thousand dollars, or leave it where it is and get nothing. Since there is no perceivable difference between adjacent settings, it is apparently rational to advance the setting each day. But at the end of ten years the pain is so great that a rational person would sacrifice all his wealth to return to the first setting.

We can view the situation here as a multi-player PD in which each "player" is the temporal stage of a single person. So viewed, it has at least two features that were not discussed in connection with the multi-player examples. First, the moves of the players are sequential rather than simultaneous (and each player has knowledge of preceding moves). Second, there is the matter of gradation. Increases in electric current between adjacent settings are imperceptible, and therefore irrelevant to rational decision-making, but sums of a number such increases are noticeable and highly relevant. Neither of these features, however, is peculiar to one-person examples. Consider, for example, the choice between a polluting and non-polluting means of waste disposal. Each resident of a lakeside community may dump his or her garbage in the lake or use a less convenient landfill. It is reasonable to suppose that each acts in the knowledge of how others have acted before. (See "Asynchronous Moves" below.) It is also reasonable to suppose that addition of one can of garbage to the lake has no perceptible effect on water quality, and therefore no effect on the welfare of the residents. The fact that the dilemma remains suggests that PD-like situations sometimes involve something more than a conflict between individual and collective rationality. In the one-person example, our understanding that we care more about our overall well-being than that of our temporal stages does not (by itself) eliminate the argument that it is rational to continue to adjust the setting. Similarly, in the pollution example, a decision to let collective rationality override individual rationality may not eliminate the argument for excessive dumping. It seems appropriate, however, to separate this issue from that raised in the standard PD. Gradations that are imperceptible individually, but weighty en masse give rise to intransitive preferences. This is a challenge to standard accounts of rationality whether or not it arises in a PD-like setting.

Cardinal Payoffs

If the game specifies absolute (as opposed to relative) payoffs, then universal cooperation may not be a pareto optimal outcome even in the two person PD. For under some conditions both players do better by adopting a *mixed* strategy of cooperating with probability p and defecting with probability (1-p). This point is illustrated in the graphs below.

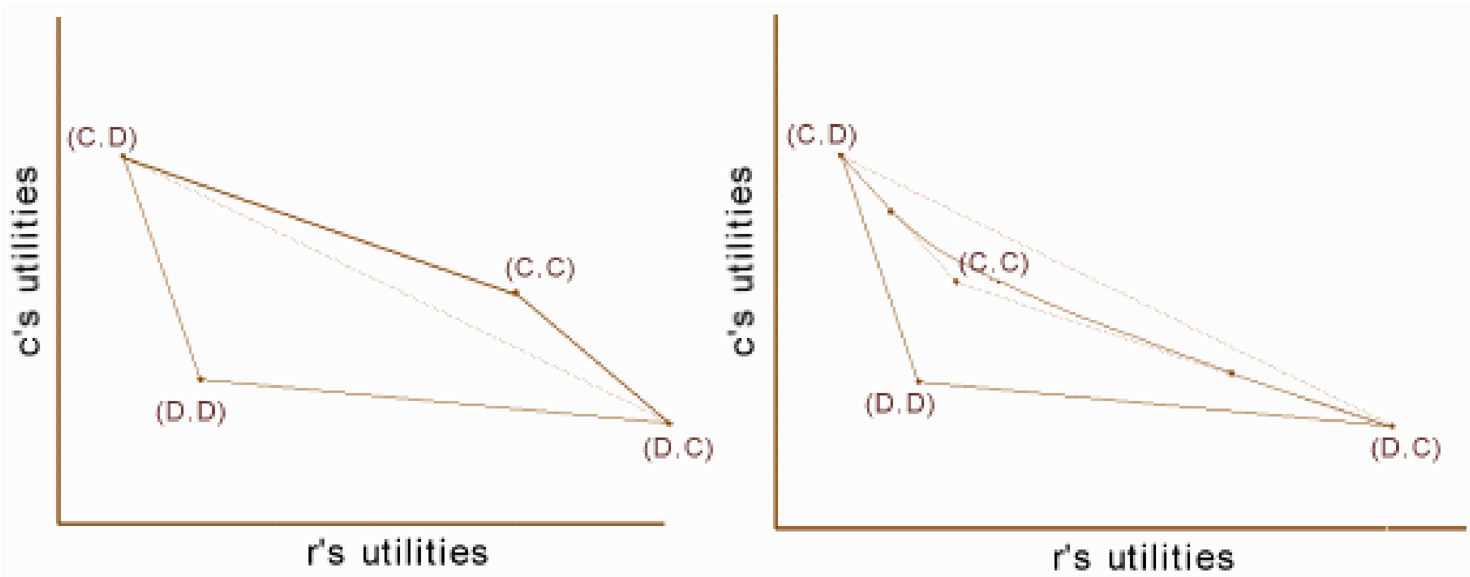

Figure 1

Here the x and y axes represent the utilities of Row and Column. The four outcomes entered in the matrix of the second section are represented by the labeled dots. Conditions PD3a and PD3b ensure that (**C**,**D**) and (**D**,**C**) lie northwest and southeast of (**D**,**D**), and PD3c is reflected in the fact that (**C**,**C**) lies northeast of (**D**,**D**). Suppose first that (**D**,**D**) and (**C**,**C**) lie on opposite sides of the line between (**C**,**D**) and (**D**,**C**), as in the graph on the left. Then the four points form a convex quadrilateral, and the payoffs of the feasible outcomes of mixed strategies are represented by all the points on or within this quadrilateral. Of course a player can really only get one of four possible payoffs each time the game is played, but the points in the quadrilateral represent the *expected values* of the payoffs to the two players. If Row and Column cooperate with probabilities p and q (and defect with probabilities p*=1-p and q*=1-q), for example, then the expected value of the payoff to Row is p*qT+pqR+p*q*P+pq*S. A rational self-interested player, according to a standard view, should prefer a higher expected payoff to a lower one. In the graph on the left the payoff for universal cooperation (with probability one) is pareto optimal among the payoffs for all mixed strategies. In the graph on the right, however, where both (**D**,**D**) and (**C**,**C**) lie southwest of the line between (**C**,**D**) and (**D**,**C**), the story is more complicated. Here the payoffs of the feasible outcome lie within a figure bounded on the northeast by three distinct curve segments, two linear and one concave. Notice that (**C**,**C**) is now in the interior of the region bounded by solid lines, indicating that there are mixed strategies that provide both players a higher expected payoff than (**C**,**C**). It is important to note that we are talking about independent mixed strategies here. Row and Column use private randomizing devices and have no communication. If they were able to correlate their mixed strategies, so as to ensure, say (**C**,**D**) with probability p and (**D**,**C**) with probability p*, the set of feasible solutions would extend up to (and include) the dotted line between (**C**,**D**) and (**D**,**C**). The point here is that, even confined to independent strategies, there are some games satisfying PD3 in which both players can both do better than they do with universal cooperation. A PD in which universal cooperation is pareto optimal may be called a pure PD. A pure PD is characterized by adding to PD3 the following condition.

P) $(T_r-R_r)(T_c-R_c) \leq (R_r-S_r)(R_c-S_c)$

In a symmetric game P reduces to the simpler condition

RCA) $R \geq 1/2(T+S)$

(named after the authors Rapoport, Chammah and Axelrod who employed it).

Asynchronous Moves

It has often been argued that rational self-interested players can obtain the cooperative outcome by making their moves conditional on the moves of the other player. Peter Danielson, for example, favors a strategy of *reciprocal cooperation*: if the other player would cooperate if you cooperate and would defect if you don't, then cooperate, but otherwise defect. Conditional strategies like this are ruled out in the versions of the game described above, but they may be possible in versions that more accurately model real world situations. In this section and the next, we consider two such versions. Here we eliminate the requirement that the two players move simultaneously. Consider the situation of a firm whose sole competitor has just lowered prices. Or suppose the buyer of a car has just paid the agreed purchase price and the seller has not yet handed over the title. We can think of these as situations in which one player has to choose to cooperate or defect after the other player has already made a similar choice. The corresponding game is an *asynchronous* or *extended* PD.

Careful discussion of an asynchronous PD example, as Skyrms (1998) and Vanderschraaf recently note, occurs in the writings of David Hume, well before Flood and Dresher's formulation of the ordinary PD. Hume writes about two neighboring grain farmers:

> Your corn is ripe today; mine will be so tomorrow. ’Tis profitable for us both, that I shou'd labour with you to-day, and that you shou'd aid me to-morrow. I have no kindness for you, and know you have as little for me. I will not, therefore, take any pains on your account; and should I labour with you upon my own account, in expectation of a return, I know I shou'd be disappointed, and that I shou'd in vain depend upon your gratitude. Here then I leave you to labour alone: You treat me in the same manner. The seasons change; and both of us lose our harvests for want of mutual confidence and security.

In deference to Hume, Skyrms and Vanderschraaf refer to this kind of asynchronous PD as the "farmer's dilemma." It is instructive to picture it in a tree diagram.

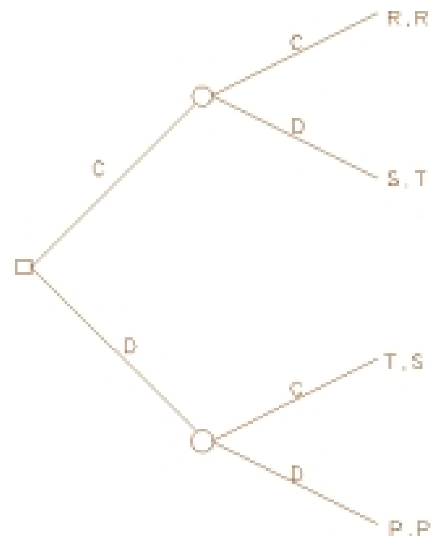

Figure 2

Here, time flows to the right. The node marked by a square indicates Player One's choice point, those marked by circles indicate when Player Two's. The moves and the payoffs to each player are exactly as in the ordinary PD, but here Player Two can choose his move according to what Player One does. Tree diagrams like Figure 2 are said to be *extensive-form* game representations, whereas the payoff matrices given previously are *normal-form* representations. As Hume's analysis indicates, making the game asynchronous does not remove the dilemma. Player One knows that if he were to choose C on the first move, Player Two would choose D on the second move (since she prefers the temptation to the reward), so he would himself end up with the sucker payoff. If Player One were to choose D, Player Two would still choose D (since she prefers the punishment to the sucker payoff), and he would end up with the punishment payoff. Since he prefers the punishment payoff to the sucker payoff, Player One will choose D on the first move and both players will end up with the payoff. This kind of "backwards" reasoning, in which the players first evaluate what would happen on the last move if various game histories were realized, and use this to determine what would happen on preceding moves applies quite broadly to games in extensive form, and a more general version of it will be discussed under iterated games below.

The farmer's dilemma can be represented in normal form by understanding Player One to be choosing between **C** and **D** and Player Two to be (simultaneously) choosing among four conditional moves: cooperate unconditionally (**Cu**), defect unconditionally (**Du**), imitate Player One's move (**I**), and do the opposite of Player One's move (**O**). The result is a two player game with the following matrix.

	Cu	**Du**	**I**	**O**
C	R,R	S,T	R,R	S,T
D	T,S	P,P	P,P	T,S

The reader may note that this game is a (multiple-move) equilibrium dilemma. The sole nash equilibrium results when Player One chooses **D** and Player Two chooses **Du**, thereby achieving for themselves the inferior payoffs of P and P. The game is not, however, a dominance dilemma. Indeed, there is no dominant move for either player. It is commonly believed that rational self-interested players will reach a nash

equilibrium even when neither player has a dominant move. If so, the farmer's dilemma is still a dilemma.

To preserve the symmetry between the players that characterizes the ordinary PD, we may wish to modify the asynchronous game. Let us take extended PD to be played in stages. First each player chooses a first move (**C** or **D**) and a second move (**Cu**, **Du**, **I** or **O**). Next a referee determines who moves first, giving each player an equal chance. Finally the outcome is computed in the appropriate way. For example, suppose Row plays (**D**,**O**) (meaning that he will defect if he moves first and do the opposite of his opponent if he moves second) and Column plays (**C**,**Du**). Then Row will get P if he goes first and T if he goes second, which implies that his expected payoff is 1/2(P+T). Column will get S if she goes first and P if she goes second, giving her an expected payoff of 1/2(P+S). It is straightforward, but tedious, to calculate the entire eight by eight payoff matrix. After doing so, the reader may observe that, like the farmer's dilemma, the symmetric form of the extended PD is an equilibrium dilemma, but not a dominance dilemma. The sole nash equilibrium occurs when both players adopt the strategy (**D**, **Du**), thereby achieving the inferior payoffs of (P,P).

Transparency

Another way that conditional moves can be introduced into the PD is by assuming that players have the property that David Gauthier has labeled *transparency*. A fully transparent player is one whose intentions are completely visible to others. Nobody holds that we humans are fully transparent, but the observation that we can often successfully predict what others will do suggests that we are at least "translucent." Furthermore agents of larger scale, like firms or countries, may be more transparent than we are. Thus there may be some theoretical interest in investigations of PDs with transparent players. Such players could presumably execute conditional strategies more sophisticated than those of the (non**-** transparent)extended game players, strategies, for example that are conditional on the conditional strategies employed by others. There is some difficulty, however, in determining exactly what strategies are feasible for such players. Suppose Row adopted the strategy "do the same as Column" and Column adopted the strategy "do the opposite of Row". There is no way that both these strategies could be satisfied. On the other hand, if each adopted the strategy "imitate the other player", there are two ways the strategies could be satisfied, and there is no way to determine which of the two they would adopt. Nigel Howard, who was probably the first to study such conditional strategies systematically, avoided this difficulty by insisting on a rigidly typed hierarchy of games. At the base level we have the ordinary PD game, where each player chooses between **C** and **D**. For any game G in the hierarchy we can generate two new games RG and CG. In RG, Column has the same moves as in game G and Row can choose any function that assigns **C** or **D** to each of Column's possible moves. Similarly in CG, Row has the same moves as in G and Column has a new set of conditional moves. For example, if [PD] is the base level game, then C[PD] is the game in which Column can choose from among the strategies **Cu**, **Du**, **I** and **O** mentioned above. Howard observed that in the two third level games RC[PD] and CR[PD] (and in every higher level game) there is an equilibrium outcome giving each player R. In particular, such an equilibrium is reached when one player plays **I** and the other cooperates when his opponent plays **I** and defects when his opponent plays **Cu**, **Du** or **O**. Notice that this last strategy is tantamount to Danielson's *reciprocal cooperation*.

The lesson of all this for rational action is not clear. Suppose two players in a PD were sufficiently

transparent to employ the conditional strategies of higher level games. How do they decide what level game to play? Who chooses the imitation move and who chooses reciprocal cooperation? To make a move in a higher level game is presumably to form an intention observable by the other player. But why should either player expect the intention to be carried out if there is benefit in ignoring it?

Conditional strategies have a more convincing application when we take our inquiry as directed, not towards playing the PD, but as designing agents who would play it well with a variety of likely opponents. This is the viewpoint of Danielson. A conditional strategy is not an intention that a player forms as a move in a game, but a deterministic algorithm defining a kind of player. Indeed, one of the lessons of the PD may be that transparent agents are better off if they can form irrevocable "action protocols" rather than always following the intentions they may form at the time of action. Danielson does not limit himself *a priori* to strategies within Howard's hierarchy. An agent is simply a computer program, which can contain lines permitting other programs to read and execute it. We could easily write two such programs, each designed to determine whether its opponent plays C or **D** and to do the opposite. What happens when these two play a PD depends on the details of implementation, but it is likely that they will be "incoherent," i.e., they will enter endless loops and be unable to make any move at all. To be successful a program *should* be able to move when paired with a variety of other programs, including copies of itself, and it should be able to get valuable outcomes. Programs implementing **I** and **O** in a straightforward way are not likely to succeed because when paired with each other they will be incoherent. Programs implementing **Du** are not likely to succeed because they get only P when paired with their clones. Those implementing **Cu** are not likely to succeed because they get only S when paired with programs that recognize and exploit their unconditionally cooperative nature. There is some vagueness in the criteria of success. In Howard's scheme we could compare a conditional strategy with all the possible alternatives of that level. Here, where any two programs can be paired, that approach is senseless. Nevertheless, certain programs seem to do well when paired with a wide variety of players. One is a version of the strategy that Gauthier has advocated as *constrained maximization*. The idea is that a player j should cooperate if the other would cooperate if j did, and defect otherwise. As stated, this appears to be a strategy for the RC[PD] or CR[PD] games. It is not clear how a program implementing it would move (if indeed it does move) when paired with itself. Danielson is able to construct an approximation to *constrained maximization*, however, that does cooperate with itself. Danielson's program (and other implementations of *constrained maximization*) cannot be coherently paired with everything. Nevertheless it does move and score well against familiar strategies. It cooperates with **Cu** and itself and it defects against **Du**. If it is coherently paired it seems guaranteed a payoff no worse than P.

A second successful program models Danielson's *reciprocal cooperation*. Again, it is not clear that the strategy (as formulated above) allows it to cooperate (or make any move) with itself, but Danielson is able to construct an approximation that does. The (approximate) *reciprocal cooperation* does as well as (approximate) *constrained maximization* against itself, **Du** and *constrained maximization*. Against **Cu** it does even better, getting T where *constrained maximization* got only R.

Iteration

Many of the situations that are alleged to have the structure of the PD, like defense appropriations of

military rivals or price setting for duopolistic firms are better modeled by an iterated version of the game in which players play the PD repeatedly, retaining access at each round to the results of all previous rounds. In these iterated PDs (hence forth IPDs) players who defect in one round can be "punished" by defections in subsequent rounds and those who cooperate can be rewarded by cooperation. Thus the appropriate strategy for rationally self-interested players is no longer obvious. The theoretical answer to this question, it turns out, depends strongly on the definition of IPD employed and the knowledge attributed to rational players.

An IPD can be represented in extensive form by a tree diagram like the one for the farmer's dilemma above.

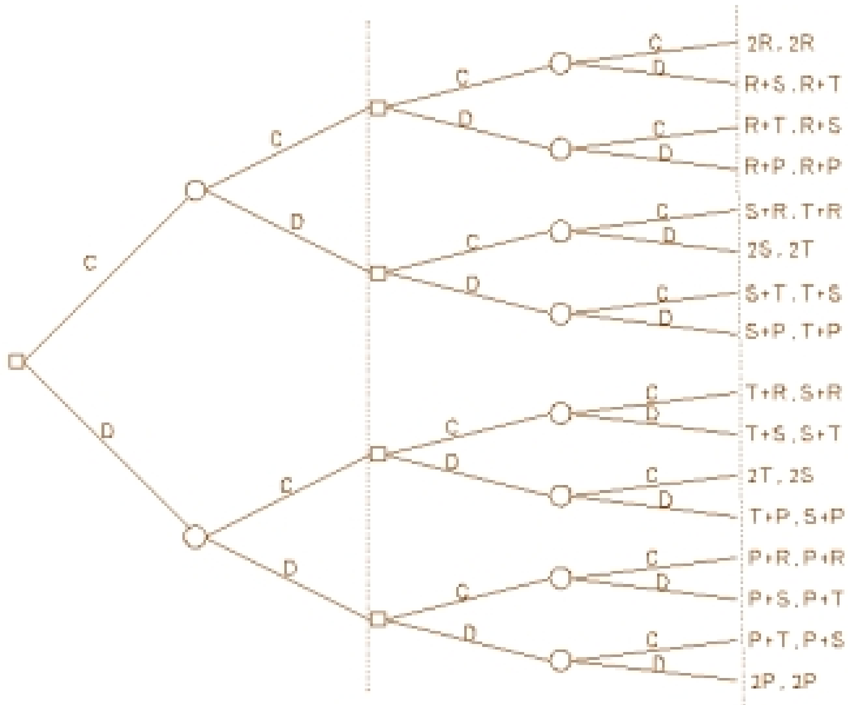

Figure 3

Here we have an IPD of length two. The end of each of the two rounds of the game is marked by a dotted vertical line. The payoffs to each of the two players (obtained by adding their payoffs for the two rounds) are listed at the end of each path through the tree. The representation differs from the previous one in that the two nodes on each branch within the same division mark simultaneous choices by the two players. Since neither player knows the move of the other at the same round, the IPD does not qualify as one of the game theorist's standard "games of perfect information." If the players move in succession rather than simultaneously (which we might indicate by removing the dotted vertical lines), the resulting game is an iterated farmer's dilemma, which does meet the game theorist's definition and which shares many of the features that make the IPD interesting.

Like the farmer's dilemma, an IPD can, in theory, be represented in normal form by taking the players' moves to be *strategies* telling them how to move if they should reach any node at the end of a round of the game tree. Like the farmer's dilemma, an IPD can, in theory, be represented in normal form by taking the players' moves to be strategies telling them how to move at each node of the game tree. The number of strategies increases very rapidly with the length of the game so that it is impossible in practice to write out the normal form for all but the shortest IPD's. Every pair of strategies determines a "play" of the game, i.e.,

a path through the extensive-form tree.

In a game like this, the notion of nash equilibrium loses some of its privileged status. Recall that a pair of moves is a nash equilibrium if each is a best reply to the other. Let us extend the notation used in the discussion of the asynchronous PD and let **Du** be the strategy that calls for defection at every node of an IPD. It is easy to see that **Du** and **Du** form a nash equilibrium. But against **Du**, a strategy that calls for defection unless the other player cooperated at, say, the fifteenth node, would determine the same play (and therefore the same payoffs) as **Du** itself does. The components that call for cooperation never come into play, because the other player does not cooperate on the fifteenth (or any other) move. Similarly, a strategy calling for cooperation after the second cooperation by itself does equally well. Thus these strategies and many others form nash equilibria with **Du**. There is a sense in which these strategies are clearly not equally rational. Although they yield the same payoffs at the nodes along the path representing the actual play, they would not yield the same payoffs if other nodes had been reached. If Player One *had* cooperated in the past, that would still provide no good reason for him to cooperate now. A nash equilibrium requires only that the two strategies are best replies to each other as the game actually develops. A stronger solution concept for extensive-form games requires that the two strategies would still be best replies to each other no matter what node on the game tree were reached. This notion of *subgame-perfect equilibrium* is defined and defended in Selten, 1975. It can be expressed by saying that the strategy-pair is a nash equilibrium for every subgame of the original game, where a subgame is the result of taking a node of the original game tree as the root, pruning away everything that does not descend from it.

Given this new, stronger solution concept, we can ask about the solutions to the IPD. There is a significant theoretical difference on this matter between IPDs of fixed, finite length, like the one pictured above, and those of infinite or indefinitely finite length. In games of the first kind, one can prove by an argument known as *backwards induction* that **Du**,**Du** is the only subgame perfect equilibrium. Suppose the players know the game will last exactly *n* rounds. Then, no matter what node have been reached, at round n-1 the players face an ordinary ("one-shot") PD, and they will defect. At round n-2 the players know that, whatever they do now, they will both defect at the next round. Thus it is rational for them to defect now as well. By repeating this argument sufficiently many times, the rational players deduce that they should defect at every node on the tree. Indeed, since at every node defection is a best response to any move, there can be no other subgame-perfect equilibria.

In practice, there is not a great difference between how people behave in long fixed-length IPDs (except in the final few rounds) and those of indeterminate length. This suggests that some of the rationality and common knowledge assumptions used in the backwards induction argument (and elsewhere in game theory) are unrealistic. There is a considerable literature attempting to formulate the argument carefully, examine its assumptions, and to see how relaxing unrealistic assumptions might change the rationally acceptable strategies in the PD and other games of fixed length. (For a small sample, see Bovens, Kreps *et al*, Kreps and Wilson, Pettit and Sugden, Selten 1978, Rabinowicz, and Binmore 1997).

Player One's belief that there is a slight chance that Two might pursue an "irrational" strategy other than continual defection could make it rational for her to cooperate frequently herself. Indeed, even if One were certain of Two's rationality, One's belief that there was some chance that Two believed she harbored such doubts could have the same effect. Thus the argument for continual defection in the IPD of fixed length

depends on complex iterated claims of certain knowledge of rationality. An even more unrealistic assumption, noted by Rabinowicz and others, is that each player continue to believe that the other will choose rationally on the next move even after evidence of irrational play on previous moves. For example, it is assumed that, at the node reached after a long series of moves (C,C), ...,(C,C), Player One will choose D despite never having done so before.

Some have used these kinds of observation to argue that the backwards induction argument shows that standard assumptions about rationality (with other plausible assumptions) are inconsistent or self-defeating. For (with plausible assumptions) one way to ensure that a rational player will doubt one's own rationality is to behave irrationally. In the fixed-length IPD, for example, Player One may be able to deduce that, if she were to follow an appropriate "irrational" strategy, Player Two would rationally react so that they can achieve mutual cooperation in almost all rounds. So our assumptions seem to imply both that Player One should continually defect and that she would do better if she didn't. (See Skyrms 1990, pp. 125-139 and Bicchieri 1989.)

Infinite Iteration

One way to avoid the dubious conclusion of the backwards induction argument without delving too deeply into conditions of knowledge and rationality is to consider infinitely repeated PD's. No human agents can actually play an infinitely repeated game, of course, but the infinite IPD has been considered an appropriate way to model a series of interactions in which the participants never have reason to think the current interaction is their last. In this setting a pair of strategies determines an infinite path through of the game tree. If the payoffs of the one-shot game are positive, their total along any such path is infinite. This makes it somewhat awkward to compare strategies. If we confine ourselves to those strategies that can be implemented by mechanical devices (with finite memories and speeds of computation), however, it turns out that the sequence of payoffs to each player will always, after a finite number of rounds, cycle repeatedly through a particular finite sequence of payoffs. The relative value of such infinite sequences of payoffs can then be identified with the average value of the payoffs in one cycle. This value reflects the limit of average payoff per round as the number of rounds increases. (See Binmore 1992, page 365 for further justification.) Since there is no last round, it is obvious that backwards induction does not apply to the infinite IPD.

Indefinite Iteration

Most contemporary investigations the IPD take it to be neither infinite nor of fixed finite length but rather of indeterminate length. This is accomplished by including in the game specification a probability p (the "shadow of the future") such that at each round the game will continue with probability p. Alternatively, a "discount factor" p is applied to the payoffs after each round so that present payoffs are valued more highly than future. Mathematically, it makes little difference whether p is regarded as a probability of continuation or a discount on payoffs. The value of cooperation at a given stage in an IPD clearly depends on the odds of meeting one's opponent in later rounds. (This has been said to explain why the level of courtesy is higher in a village than a metropolis and why customers tend leave better tips in local restaurants than distant ones.) As p approaches zero, the IPD becomes a one-shot PD, and the value of defection increases. As p approaches one the IPD becomes an infinite IPD, and the value of defection decreases. It is also customary

to insist that the game has the property labeled RCA above, so that (in the symmetric game) players do better by cooperating on every round than they would do by "taking turns" -- you cooperate while I defect and then I cooperate while you defect.

There is a controversial claim, originating in Kavka and Sobel and still repeated, that the backwards induction argument applies even to indefinitely repeated IPD's, as long as an upper bound to the length of the game is common knowledge. For if b is such an upper bound, then if the players were to get to stage b they would know that it was the last round and they would defect; if they were to get to stage b-1 they would know that their behavior on this round cannot affect the decision to defect on the next, and so they would defect; and so on. It is an easy matter to compute upper bounds on the number of interactions in real-life situations. For example, since shopkeeper Jones cannot make more than one sale a second and since he will live less than a thousand years, he and customer Smith can calculate that they cannot possibly conduct more than 10^{12} transactions. The Kavka-Sobel argument, however, seems to rest not just on common knowledge of an upper bound, but common knowledge of a "sharp" upper bound. Although there is zero probability of 10^{12}+1 interactions between Jones and Smith, the probability of the counterfactual "If there were 10^{12} interactions, there would be another" is not zero. Any world odd enough to have permitted 10^{12} interactions is very likely to permit 10^{12}+1. So the backwards induction cannot get started. As we have seen, the in standard treatment of the indefinite IPD it is assumed that there is a finite probability p of the game's continuing at each stage t. Becker and Cudd suggest that the constant p be replaced by a function p(t) that decreases at each round of the game. If p(t) gets sufficiently low then the Kavka-Sobel backwards induction argument does go through. For each IPD, however, there is a threshold p such that as long p(t) always remains above p, the game will admit cooperative solutions. (It is important in this context to give p(t) the counterfactual interpretation suggested above. To take it--as Becker and Cudd appear to do--as the conditional probability of the game's reaching t+1 given that it has reached t is to deny the Kavka-Sobel assumption that there is a stage that can be reached with probability zero.)

The iterated version of the PD was discussed from the time the game was devised, but interest accelerated after influential publications of Robert Axelrod in the early eighties. Axelrod invited professional game theorists to submit computer programs for playing IPDs. All the programs were entered into a tournament in which each played every other (as well as a clone of itself and a strategy that cooperated and defected at random) hundreds of times. It is easy to see that in a game like this no strategy is "best" in the sense that its score would be highest among any group of competitors. If the other strategies never consider the previous history of interaction in choosing their next move, it would be best to defect unconditionally. If the other strategies all begin by cooperating and then "punish" any defection against themselves by defecting on all subsequent rounds, then a policy of unconditional cooperation is better. Nevertheless, as in the transparent game, some strategies have features that seem to allow them to do well in a variety of environments. The strategy that scored highest in Axelrod's initial tournament, Tit for Tat (henceforth **TFT**), simply cooperates on the first round and imitates its opponent's previous move thereafter. More significant than **TFT**'s initial victory, perhaps is the fact that it won Axelrod's second tournament, whose sixty three entrants were all given the results of the first tournament. In analyzing the his second tournament, Axelrod noted that each of the entrants could be assigned one of five "representative" strategies in such a way that a strategy's success against a set of others can be accurately predicted by its success against their representative. As a further demonstration of the strength of **TFT**, he calculated the scores each strategy would have received in tournaments in which one of the representative strategies was five times as common as in the original

tournament. **TFT** received the highest score in all but one of these hypothetical tournaments.

Axelrod attributed the success of **TFT** to four properties. It is *nice*, meaning that it is never the first to defect. The eight nice entries in Axelrod's tournament were the eight highest ranking strategies. It is *retaliatory*, making it difficult for it to be exploited by the rules that were not nice. It is *forgiving*, in the sense of being willing to cooperate even with those who have defected against it (provided their defection wasn't in the immediately preceding round). An unforgiving rule is incapable of ever getting the reward payoff after its opponent has defected once. And it is *clear*, presumably making it easier for other strategies to predict its behavior so as to facilitate mutually beneficial interaction.

Suggestive as Axelrod's discussion is, it is worth noting that the ideas are not formulated precisely enough to permit a rigorous demonstration of the supremacy of **TFT**. One doesn't know, for example, the extent of the class of strategies that might have the four properties outlined, or what success criteria might be implied by having them. It is true that if one's opponent is playing **TFT** (and the shadow of the future is sufficiently large) then one's maximum payoff is obtained by a strategy that results in mutual cooperation on every round. Since **TFT** is itself one such strategy this implies that **TFT** forms a nash equilibrium with itself in the space of all strategies. But that does not particularly distinguish **TFT**, for **Du**, **Du** is also a nash equilibrium. Indeed, a "folk theorem" of iterated game theory (now widely published -- see, for example, Binmore 1992, pp. 373-377) implies that, for any p, $0 \leq p \leq 1$ there is a nash equilibrium in which p is the fraction of times that mutual cooperation occurs. Indeed **TFT** is, in some respects, *worse* than many of these other equilibrium strategies, because the folk theorem can be sharpened to a similar result about subgame perfect equilibria. And **TFT**, **TFT** is, in general, *not* subgame perfect. For, were one **TFT** player (*per impossible*) to defect against another, the second would have done better as an unconditional cooperator.

Iteration With Error

In a survey of the field several years after the publication of the results reported above, Axelrod and Dion, chronicle several successes of **TFT** and modifications of it. They conclude that "research has shown that many of Axelrod's findings...can be generalized to settings that are quite different from the original two-player iterated Prisoner's Dilemma game." But in several reasonable settings **TFT** has serious drawbacks. One such case, noted in the Axelrod and Dion survey, is when attempts are made to incorporate the plausible assumption that players are subject to errors of execution and perception. There are a number of ways this can be done. Bendor, for example, considers "noisy payoffs." When a player cooperates while its opponent defects its payoff is S+e, where e is a random value whose expected value is 0. Each player infers the other's move from its own payoff, and so if e is sufficiently high its inference may be mistaken. Sugden (pp 112-115) considers players who have a certain probability of making an error of execution that is apparent to them but not their opponents. Such players can adopt strategies by which they "atone" for mistaken defections by being more cooperative on later rounds than they would be after intended defection. Assuming that players themselves cannot distinguish a mistaken move or observation from a real one, however, the simplest way to model the inevitability of error is simply to forbid completely deterministic strategies like **TFT**, replacing them with "imperfect" counterparts, like "imitate the other player's last move with 99% probability and oppose it with 1% probability." **Imperfect TFT** is much less attractive than its

deterministic sibling, because when two **imperfect TFT** strategies play each other, an "error" by either one will set off a long chain of moves in which the players take turns defecting. In a long iterated game between two **imperfect TFT**'s with any probability *p* of error, $0 < p < 1/2$, players will approach the same average payoffs as in a game between two strategies that choose randomly between cooperation and defection, namely 1/4(R+P+S+T). That is considerably worse than the payoff of R, that results when *p*=0.

The predominant view seems to be that, when imperfection is inevitable, successful strategies will have to be more forgiving of defections by their opponents (since those defections might well be unintended). Molander 1985 demonstrates that strategies that mix **TFT** with **Cu** do approach a payoff of R as the probability of error approaches zero. When these mixes play each other, they benefit from higher ratios of **Cu** to **TFT**, but if they become too generous, they risk exploitation by "stingy" strategies that mix **TFT** with defection. Molander calculates that when the mix is set so that, following a defection, one cooperates with probability g(R,P,T,S)=min{1-(T-R)/(R-S), (R-P)/(T-P)}, the generous strategies will get the highest score with each other that is possible without allowing stingy strategies to do better against them than TFT does. Following Nowak and Sigmund, we label this strategy **generous TFT**, or **GTFT**.

The idea that the presence of imperfection induces greater forgiveness or generosity is only plausible for low levels of imperfection. As the level of imperfection approaches 1/2, **Imperfect TFT** becomes indistinguishable from the random strategy, for which the very ungenerous **Du** is the best reply. A simulation by Kollock seems to confirm that at high levels of imperfection, more stinginess is better policy than more forgiveness. But Bendor, Kramer and Swistak note that the strategies employed in the Kollock simulation are not representative and so the results must be interpreted with caution.

A second idea is that an imperfect environment encourages strategies to observe their opponent's play more carefully. In a tournament similar to Axelrod's (Donninger) in which each player's moves were subject to a 10% chance of alteration, **TFT** finished sixth out twenty-one strategies. As might have predicted on the dominant view, it was beaten by the more generous **Tit-for-Two-Tats** (which cooperates unless defected against twice in a row). It was also beaten, however, by two versions of **Downing**, a program that bases each new move on its best estimate how responsive its opponent has been to its previous moves. In Axelrod's two original tournaments, **Downing** had ranked near the bottom third of the programs submitted. Bendor (1987) demonstrates deductively that against imperfect strategies there are advantages to basing one's probability of defection on longer histories than does **TFT**.

One clever implementation of the idea that a strategies in an imperfect environment should pay attention to their previous interactions is the family of "Pavlovian" strategies investigated by Kraines and Kraines. For each natural number *n*, *n*-Pavlov, or $\mathbf{P}_n$, adjusts its probability of cooperation in units of 1/*n*, according to how well it fared on the previous round. More precisely, if $\mathbf{P}_n$ was cooperating with probability p on the last round, then on this round it will cooperate with probability p[+](1/*n*) if it received the reward payoff on the previous round, p[-](1/*n*) if it received the punishment payoff, p[+](2/*n*)if it received the temptation payoff, and p[-](2/*n*) if it received the sucker payoff. [+] and [-] are bounded addition and subtraction, i.e., x[+]y is the sum x+y unless that number exceeds one, in which case it is one (or as close to one as the possibility of error allows), and x[-]y is similarly either x-y or close to zero. Strictly speaking, $\mathbf{P}_n$ is not fully specified until an initial probability of cooperation is given, but for most purposes the value of that parameter

becomes insignificant in sufficiently long games and can be safely ignored. It may appear that $\mathbf{P}_n$ requires far more computational resources to implement than, say, **TFT**. Each move for the latter depends on only on its opponent's last move, whereas each move for $\mathbf{P}_n$ is a function of the entire history of previous moves of both players. $\mathbf{P}_n$, however, can always calculate its next move by tracking only its current probability of cooperation and its last payoff. As its authors maintain, this seems like "a natural strategy in the animal world." One can calculate that for n>1, $\mathbf{P}_n$ does better against the random strategy than does **TFT**. More generally, $\mathbf{P}_n$ does as well or better than **TFT** against the generous unresponsive strategies **Cp** that always cooperate with fixed probability p $\geq$ 1/2 (because an occasional temptation payoff can teach it to exploit the unresponsive strategies.) In these cases the "slow learner" versions of Pavlov with higher values of *n* do slightly better than the "fast learners" with low values. Against responsive strategies, like other Pavlovian strategies and **TFT**, $\mathbf{P}_n$ and its opponent eventually reach a state of (almost) constant cooperation. The total payoff is then inversely related to the "training time," i.e., the number of rounds required to reach that state. Since training time of $\mathbf{P}_n$ varies exponentially with n, Kraines and Kraines maintain that $\mathbf{P}_3$ or $\mathbf{P}_4$ are to be preferred to other Pavlovian strategies, and are close to "ideal" IPD strategies. It should be noted, however, that when (deterministic) **TFT** plays itself, no training time at all is required, whereas when a Pavlovian strategy plays **TFT** or another Pavlov, the training time can be large. Thus the cogency of the argument for the superiority of Pavlov over **TFT** depends on the observation that its performance shows less degradation when subject to imperfections. It is also worth remembering that no strategy is best in every environment, and the criteria used in defense of various strategies in the IPD are vague and heterogeneous. One advantage of the evolutionary versions of the IPD discussed in the next section is that they permit more careful formulation and evaluation of success criteria.

Evolution

Perhaps the most active area of research on the PD concerns evolutionary versions of the game. A population of players employing various strategies play IPDs among themselves. The lower scoring strategies decrease in number, the higher scoring increase, and the process is repeated. Thus success in an evolutionary PD (henceforth EPD), requires doing well with other successful strategies, rather than doing well with a wide range of strategies.

The initial population in an EPD can be represented by a set of pairs $\{(p_1,s_1),...(p_n,s_n)\}$ where $p_1,...,p_n$ are the proportions of the population playing strategies $s_1,...,s_n$, respectively. The description of EPD's given above does not specify exactly how the population of strategies is to be reconstituted after each IPD. The usual assumption, and the most sensible one for biological applications, is that a score in any round indicates the relative number of "offspring" in the next. It is assumed that the size of the entire population stays fixed, so that births of more successful strategies are exactly offset by deaths of less successful ones. This amounts to the condition that the proportion p_i* of each strategy s_i in the successor population is determined by the equation $p_i^*=p_i(V_i/V)$, where V_i is the score of s_i in the previous round and V is the average of all scores in the population. Thus every strategy that scores above the population average will increase in number and every one that scores below the average will decrease. This kind of evolution is referred to as "replication dynamics" or evolution according to the "proportional fitness" rule. Other rules of

evolution are possible. Bendor and Swistak argue that, for social applications, it makes more sense to think of the players as switching from one strategy to another rather than as coming into and of existence. Since rational players would presumably switch only to strategies that received the highest payoff in previous rounds, only the highest scoring strategies would increase in numbers. Discussion here, however will primarily concern EPDs with the proportional fitness rule.

Axelrod, borrowing from Trivers and Maynard Smith, includes a description of the EPD with proportional fitness, and a brief analysis of the evolutionary version of his IPD tournament. For Axelrod, the EPD provides one more piece of evidence in favor of **TFT**:

> TIT FOR TAT had a very slight lead in the original tournament, and never lost this lead in simulated generations. By the one-thousandth generation it was the most successful rule and still growing at a faster rate than any other rule.

Axelrod's EPD tournament, however, incorporated several features that might be deemed artificial. First, it permitted deterministic strategies in a noise-free environment. As noted above, **TFT** can be expected to do worse under conditions that model the inevitability of error. Second, it began with only the 63 strategies from the original IPD tournament. Success against strategies concocted in the ivory tower may not imply success against all those that might be found in nature. Third, the only strategies permitted to compete at a given stage were the survivors from the previous stage. A more realistic model, one might argue, would allow new "mutant" strategies to enter the game at any stage. Changing this third feature might well be expected to hurt **TFT**. For a large growth in the **TFT** population would make it possible for mutants employing more naive strategies like **Cu** to regain a foothold, and the presence of these naifs in the population might favor nastier strategies like **Du** over **TFT**.

Nowak and Sigmund simulated two kinds of tournaments that avoid the three questionable features. The first examined the family of "reactive" strategies. For any probabilities y, p, and q, **R**(y,p,q) is the strategy of cooperating with probability y in the first round and thereafter with probability p if the other player has cooperated in the previous round, and with probability q if she has defected. This is a broad family, including many of the strategies already considered. **Cu**, **Du**, **TFT**, and **Cp** are **R**(1,1,1), **R**(0,0,0), **R**(1,1,0), and **R**(p,p,p). To capture the inevitability of error, Nowak and Sigmund exclude the deterministic strategies, where p and q are exactly 1 or 0, from their tournaments. As before, if the game is sufficiently long (and p and q are not integers), the first move can be ignored and a reactive strategy can be identified with its p and q values. Particular attention is paid to the strategies close to Molander's **GTFT** described above, where p=1 and q=min{1-(T-R)/(R-S), (R-P)/(T-P). The first series of Nowak and Sigmund's EPD tournaments begin with representative samples of reactive strategies. For most such tournaments, they found that evolution led irreversibly to **Du**. Those strategies **R**(p,q) closest to **R**(0,0) thrived while the others perished. When one of the initial strategies is very close to **TFT**, however, the outcome changes.

> TFT and all other reciprocating strategies (near (1,0)) seem to have disappeared. But an embattled minority remains and fights back. The tide turns when 'suckers' are so decimated that exploiters can no longer feed on them. Slowly at first, but gathering momentum, the reciprocators come back, and the exploiters now wane. But the **TFT**-like strategy that caused

> this reversal of fortune is not going to profit from it: having eliminated the exploiters, it is robbed of its mission and superseded by the strategy closest to GTFT. Evolution then stops. Even if we introduce occasionally 1% of another strategy it will vanish.

On the basis of their tournaments among reactive strategies, Nowak and Sigmund conjectured that, while **TFT** is essential for the emergence of cooperation, the strategy that actually underlies persistent patterns of cooperation in the biological world is more likely to be **GTFT**.

A second series of simulations with a wider class of strategies, however, forced them to revise their opinion. The strategies considered in the second series allowed each player to base its probability of cooperation on its own previous move as well as its opponent's. A strategy can now be represented as $\mathbf{S(p_1,p_2,p_3,p_4)}$ where p_1, p_2, p_3, p_4 are the probabilities of defecting after outcomes (**C**,**C**), (**C**,**D**), (**D**,**C**), and (**D**,**D**), respectively i.e., after receiving the reward, sucker, temptation and punishment payoffs. (Again, we can ignore the probability of defecting on the first move as long as the p_i's are not zero or one. The initial population in these tournaments all play the random strategy **S**(.5,.5,.5,.5) and after every 100 generations a small amount of a randomly chosen (non-deterministic) mutant is introduced, and the population evolves by proportional fitness. The results are quite different than before. After 10^7 generations, a state of steady mutual cooperation was reached in 90% of the simulation trials. But less than 8.3% of these states were populated by players using **TFT** or **GTFT**. The remaining 91.7% were dominated by strategies close to **S**(1,0,0,1). This is the just the Pavlovian strategy $\mathbf{P}_1$ of Kraines and Kraines, which cooperates after receiving R or T and defects after receiving P or S. Kraines and Kraines had been somewhat dismissive of $\mathbf{P}_1$. They recall that Rapoport and Chammah, who identified it early in the history of game theory had labeled it "simpleton" and remark that "the appellation is well deserved". Indeed, $\mathbf{P}_1$ has the unfortunate characteristic of trying to cooperate with **Du** on every other turn, and against **TFT** it can get locked into the inferior repeating series of payoffs T,P,S,T,P,S,... . But Nowak and Sigmund's simulations suggest that these defects do not matter very much in evolutionary contexts. One reason may be that $\mathbf{P}_1$ helps to make its environment unsuitable for its enemies. **Du** does well in an environment with generous strategies, like **Cu** or **GTFT**. **TFT**, as we have seen, allows these strategies to flourish, which could pave the way for **Du** Thus, although **TFT** fares less badly against **Du** than $\mathbf{P}_1$ does, $\mathbf{P}_1$ is better at keeping its environment free of **Du**.

Simulations in a universe of deterministic strategies yield results quite different than those of Nowak and Sigmund. Bruce Linster (1992 and 1994) suggests that natural classes of strategies and realistic mechanisms of evolution can be defined by representing strategies as simple *Moore machines*. For example, P1 is represented by the machine pictured below.

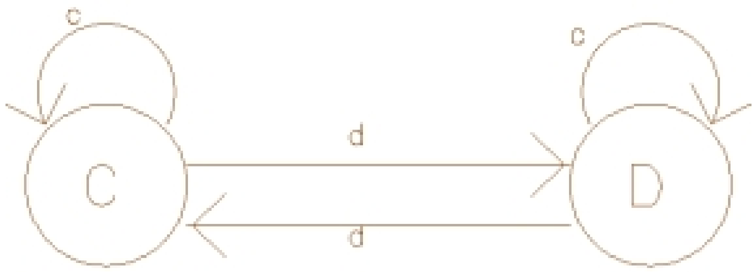

Figure 4

This machine has two states, indicated by circles. It begins in the leftmost state. The C in the left circle means that the machine cooperates on the first move. The arrow leading from the left to the right circle indicates that machine defects (enters the *D*) after it has cooperated (been in the *C* state) and its opponent has defected (the arrow is labeled by *d*). Linster has conducted simulations of evolutionary PD's among the strategies that can be represented by two-state Moore machines. It turns out that these are exactly the deterministic versions of the S strategies of Nowak and Sigmund. Since the strategies are deterministic, we must distinguish between the versions that cooperate on the first round and those that defect on the first round. Among the first round cooperators, S(0,0,0,0), S(0,0,0,1), S(0,0,1,0) and S(0,0,0,1) all represent the strategy **Cu** of unconditional cooperation. Similarly, four of the first-round defectors all represent **Du**. Each of the other **S**(p_1,p_2,p_3,p_4) where p_1, p_2, p_3, p_4 are either zero or one represent unique strategies. By deleting the six duplicates from the thirty-two deterministic versions of Nowak and Sigmund's strategies, we obtain the twenty-six "two-state" strategies considered by Linster.

Linster simulated a variety of EPD tournaments among the two-state strategies. Some used "uniform mutation" in which each strategy in the population has an equal probability *m* of mutating into any of the other strategies. Some used "stylized mutation" in which the only mutations permitted are those that can be understood as the result of a single "broken link" in the Moore machine diagrams. In some, mutations were assumed to occur to a tiny proportion of the population at each generation; in others the "mutants" represented an invading force amounting to one percent of the original population. In some, a penalty was levied for increased complexity in the form of reduced payoffs for machines requiring more states or more links. As one might expect, results vary somewhat depending on conditions. There are some striking differences, however, between all of Linster's results and those of Nowak and Sigmund. In Linster's tournaments, no single strategy ever dominated the surviving populations in the way that $\mathbf{P}_1$ and **GTFT** did in Nowak and Sigmund's. The one strategy that did generally come to comprise over fifty percent of the population was the initially-cooperating version of S(0,1,1,1). This is a strategy whose imperfect variants seem to have been remarkably uncompetitive for Nowak and Sigmund. It has been frequently discussed in the game theory literature under the label **GRIM** or **TRIGGER**. It cooperates until its opponent has defected once, and then defects for the rest of the game. According to Skyrms (1998) and Vanderschraaf, both Hobbes and Hume identified it as the strategy that underlies our cooperative behavior in important PD-

like situations. The explanation for the discrepancy between **GRIM's** performance for Linster and for Nowak and Sigmund probably has to do with its sharp deterioration in the presence of error. In a match between two imperfect **GRIM**s, an "erronious" defection by either leads to a long string of mutual defections. Thus, in the long run imperfect **GRIM** does poorly against itself. The other strategies that survived (in lesser numbers) Linster's tournaments are **TFT**, $\mathbf{P}_1$, **Cu**, and the initially-cooperative S(0,1,1,0). (Note that imperfect **GRIM** is also likely to do poorly against imperfect versions of these.) The observation that evolution might lead to a stable mix of strategies (perhaps each serving to protect others against particular types of invaders) rather than a single dominant strategy is suggestive. Equally suggestive is the result obtained under a few special conditions in which evolution leads to a recurring cycle of population mixes.

One might expect it to be possible to predict the strategies that will prevail in EPDs meeting various conditions, and to justify such predictions by formal proofs. Until recently, however, mathematical analyses of the EPD have been plagued by conceptual confusions about "evolutionary stability," the condition under which, as Nowak and Sigmund say, "evolution stops". Axelrod and Axelrod & Hamilton claim to show that **TFT** is evolutionarily stable. Selten 1983, includes an example of a game with no evolutionarily stable strategy, and Selten's argument that there is no such strategy clearly applies to the **EPD** and other evolutionary games. Boyd and Lorberbaum and Farrell and Ware present still different proofs demonstrating that no strategies for the **EPD** are evolutionarily stable. Unsurprisingly, the paradox is resolved by observing that the three groups of authors each employ slightly different conceptions of evolutionary stability. The conceptual tangle is unraveled in a series of papers by Bendor and Swistak. Two stability concepts are described and applied to the EPD below. Readers who wish to compare these with some others that appear in the literature may consult the following brief guide:

> Concepts of Stability in Evolutionary Games.

A strategy s for an evolutionary game has *universal strong narrow stability* ("usn-stability") if a population playing strategy s will, under any rule of evolution, drive to extinction any sufficiently small group of invaders all of which play the same strategy. An evolutionary game has usn-stability just in case it meets a simple condition on payoffs identified by Maynard Smith:

> MS) For all strategies j, V(i,i) > V(j,i) or both V(i,i)=V(j,i) and V(i,j)>V(j,j)

(Here, and in what follows, the notation V(i,j) indicates the payoff to strategy i when i plays j.) MS says that any invaders do strictly worse against the natives than the natives themselves do against the natives or else they get exactly the same payoff against the natives as the natives themselves do, but the native does better against the invader than the invader himself does.

For any strategy i in the IPD (or indeed in any iterated finite game), however, there are strategies j different from i such that j mimics the way i plays when it plays against i or j. The existence of these "neutral mutants" implies that MS cannot be satisfied and so no EPD has usn-stability. This argument, of course, uses the assumption that any strategy in the iterated game is a possible invader. There may be good reason to restrict the available strategies. For example, if the players are assumed to have no knowledge of

previous interactions, then it may be appropriate to restrict available strategies to the unconditional ones. Since a pair of players then get the same payoffs in every round of an iterated game, we may as well take each round of the evolutionary game to be one-shot games between every pair of players rather than iterated games. Indeed, this is the kind of evolutionary game that Maynard Smith himself considered. In this framework, any strategy S such that (S,S) is a strict nash equilibrium in the underlying one-shot game (including unconditional defection in the PD) meets the MS condition. Thus MS and usn-stability are non-trivial conditions in some contexts.

A strategy s has *restricted weak broad stability)* (rwb-stability) if, when evolution proceeds according to the proportional fitness rule and the native population is playing s, any (possibly heterogeneous) group of invaders of sufficiently small size will fail to drive the natives to extinction. This condition turns out to be equivalent to a weakened version of MS identified by Bendor and Swistak.

> BS) For all strategies j, $V(i,i) > V(j,i)$ or both $V(i,i)=V(j,i)$ and $V(i,j) \geq V(j,j)$

BS and rwb-stability are non-trivial conditions in the more general evolutionary framework: strategies for the EPD that satisfy rwb-stability do exist. This does not particularly vindicate any of the strategies discussed above, however. Bendor and Swistak prove a result analogous to the folk theorem mentioned previously: If the shadow of the future is sufficiently large, there are rwb-stable strategies supporting any degree of cooperation from zero to one. One way to distinguish among the strategies that meet BS is by the size of the invasion required to overturn the natives, or, equivalently, by the proportion of natives required to maintain stability. Bendor and Swistak show that this number, the *minimal stabilizing frequency*, never exceeds 1/2: no population can resist every invading group as large as itself. They maintain that this result does allow them to begin to provide a theoretical justification for Axelrod's claims. They are able to show that, as the shadow of the future approaches one, any strategy that is nice (meaning that it is never first to defect) and retaliatory (meaning that it always defects immediately after it has been defected against) has a minimal stabilizing frequency approaching one half. **TFT** has both these properties and, in fact, they are the first two of the four properties Axelrod cited as instrumental to **TFT**'s success. There are, of course, many other nice and retaliatory strategies, and there are strategies (like $\mathbf{P}_1$) that are not retaliatory but still satisfy rwb-stability. But Bendor and Swistak are at least able to show that any "maximally robust" strategy, i.e., any strategy whose minimum stabilizing frequency approaches one half, chooses cooperation on all but a finite number of moves in an infinitely repeated PD.

Bendor and Swistak's results must be interpreted with some care. First, one should keep in mind that no probabilistic or noise- sensitive strategies can fit the definitions of either "nice" or "retaliatory" strategies. Furthermore, imperfect versions of **TFT** do not satisfy rwb-stability. They can be overthrown by arbitrarily small invasions of deterministic **TFT** or, indeed, by arbitrary small invasions of any less imperfect **TFT**. Second, one must remember that the results about minimal stabilizing frequencies only concern weak stability. If the number of generations is large compared with the original population (as it often is in biological applications), a population that is initially composed entirely of players employing the same maximally robust strategy, could well admit a sequence of small invading groups that eventually reduces the original strategy to less than half of the population. At that point the original strategy could be overthrown.

It is likely that both of these caveats play some role in explaining an apparent discrepancy between the Bendor/Swistak results and the Nowak/Sigmund simulations. One would expect Bendor/Swistak's minimal stabilizing frequency to provide some indication of the length of time that a population plays a particular strategy. A strategy requiring a large invasion to overturn is likely to prevail longer than a strategy requiring only a small invasion. A straightforward calculation reveals that $\mathbf{P}_1$ has a relatively low minimum stabilizing frequency. It is overturned by invasions of unconditional defectors exceeding 10% of the population. Yet in the Nowak/Sigmund simulations, $\mathbf{P}_1$-like strategies predominate over **TFT**-like strategies. Since the simulations required imperfection and since they generated a sequence of mutants vastly larger than the original population, there is no real contradiction here. Nevertheless the discrepancy suggests that we do not yet have a theoretical understanding of EPD's sufficient to predict the strategies that will emerge under various plausible conditions.

Like usn-stability, the concept of rwb-stability can be more discriminating if it is relativized to a particular set of strategies. Molander's 1992 investigation of Schelling's many-person version of the PD, for example, restricts attention to the family $\{\mathbf{S}_1,...,\mathbf{S}_n\}$ of **TFT**-like stratgies. A player adopting $\mathbf{S}_i$ cooperates on the first round and on every subsequent round after at least i others cooperate. By construing stability as resistance to invasions by other family members, Molander is able to show that there are conditions under which a particular mix of two of the $\mathbf{S}_i$'s (one equivalent to **Du**) is uniquely stable. The significance of results like these, however, depends on the plausibility of such limitations on the set of permissible strategies.

Spatial PD's

In many social and biological situations said to be modeled by an EPD, individuals interact only with those within some geographical proximity. Areas inhabited by less successful individuals might be taken over by more successful neighbors. Alternatively, less successful individuals might adopt the strategies of their more successful neighbors. A spatial PD (SPD) attempts to add this geographical feature to the game. A small set of strategies is distributed among the cells of a grid (which may have a boundary, or be unbounded, like the surface of a sphere). At a given round the strategy in each cell plays PDs against the strategies in each of the "neighbor" cells (which may be stipulated to include the cell itself). The cell's score in that round is the sum of its payoffs in these interactions. The strategy in the cell is then replaced by the strategy of the neighbor cell with highest score, and the next round begins.

As usual, the impetus here seems to come from Axelrod. Axelrod randomly distributed four copies of each of the 63 strategies submitted to his tournament on a grid arranged so that each cell had four neighbors. For every initial random distribution, the resulting SPD eventually reached a state where the strategy in every cell was cooperating with all its neighbors, at which point no further evolution is possible. Only about ten of the 63 original strategies remained in these end-states, and they were no longer randomly distributed, but segregated into clumps of various sizes. Axelrod also showed that under special conditions evolution in an SPD can create successions of complex symmetrical patterns that do not appear to reach any steady-state equilibrium.

Nowak and May have investigated in greater detail SPD's in which the only permitted strategies are **Cu** and **Du**. (These are the strategies appropriate among individuals lacking memory or recognition skills.) They find that, for a variety of spatial configurations, and distributions of strategies evolution depends on relative payoffs in a uniform way. When the temptation payoff is sufficiently high clusters of **Du** grow and those of **Cu** shrink and when it is sufficiently low the **Du** clusters shrink and the **Cu** ones grow. For a narrow range of intermediate values, we get more of the complicated patterns noted above. The evolving patterns exhibit great variety, but for a given spatial configuration the ratio of the two strategies seems to approach the same constant value for all initial distributions of strategies and all payoffs within the special range. More recently, Nowak, Boenhoeffer and May have observed similar phenomena under a variety of error-conditions identified by Mukherji and Rajan, although cooperators seem to require lower relative temptation values to thrive under these conditions, and the level of error must be sufficiently low.

Grim, Mar and St Denis report a number of SPD simulations with a greater variety of initial strategies. In general their observations suggest that cooperative outcomes are more common in SPD's than ordinary EPD's. Simulations starting with all of the pure reactive strategies of Nowak and Sigmund (i.e., all of the strategies **R**(y,p,q) described above where y,p and q are either 0 or 1.), all ended with **TFT** (i.e., with **R**(1,1,0)) as the only survivor (though other outcomes--including one in which **Du** is the sole survivor and ones in which **Cu** and **TFT** are intermixed--are clearly possible.) Simulations of the 64 possible pure strategies in which a move may depend on the opponent's previous two moves, ended with mixed populations of survivors all of whom defect after two defections, cooperate after two cooperations and cooperate in the second round of the game. (Again, other outcomes are possible.) Simulations with many (viz., 100) evenly distributed samples of Nowak and Sigmunds mixed reactive strategies, tended to be taken over by **R**(.99,.1), which is a version of generous **TFT** with slightly less generosity than **GTFT**. Simulations beginning with a random selection of a few (viz., 8) of these strategies tended to evolve to a mixed stable or cyclic pattern dominated by a single version of generous **TFT** with considerably more generosity than **GTFT**. **R**(.99,.6) seems to have been a frequent victor.

SPD's differ from ordinary EPD's in at least two different ways. First, the "spatial" aspect of the games implies that (after the first round) players are more likely to face opponents playing the same strategies as themselves. Second, the "local winner imitation" dynamic can quickly drive to extinction strategies that would survive (and eventually dominate) under the proportional fitness rule commonly employed in EPD's. It is likely that both of these features are relevant to explain the differences between the results of SPD and EPD simulations.

At present there seems to be little theoretical understanding of the evolution of SPD's, and they have not made much contribution to biological or social theory. They have, however, given us some pretty pictures to contemplate. Several examples are accessible through the links at the end of this entry.

Stability Concepts in Evolutionary Games

Logical relations among concepts of stability used in discussions of the EPD and other evolutionary games are established in a series of papers by Bendor and Swistak. Some conditions on game payoffs and some conditions on the course of evolution are described below. Logical relations among these conditions are represented in the diagram that follows.

Conditions on payoffs

($V(i,j)$ is the total payoff that i gets playing against j.)

CS	Axelrod ("Collective Stability")	$\forall j[V(i,i) \geq V(j,i)]$
MS	Maynard Smith	$\forall j[V(i,i) > V(j,i)$ or $(V(i,i)=V(j,i)$ & $V(i,j) > V(j,j))]$
BL	Boyd and Lorberbaum	$\forall j[V(i,i) > V(j,i)$ or $(V(i,i)=V(j,i)$ & $\forall k(V(i,k) \geq V(j,k)))]$
BS	Bendor and Swistak	$\forall j[V(i,i) > V(j,i)$ or $(V(i,i)=V(j,i)$ & $V(i,j) \geq V(j,j))]$

Conditions on the course of evolution

u and r ("universal" and "restricted") indicates that the condition obtains under any rule of evolution or merely under the replication dynamics. s and w ("strong" and "weak") indicate that the strategy eradicates invasions or merely survives them. n and b ("narrow" and "broad") indicate that the invaders are homogeneous (i.e., they all employ the same strategy), or heterogeneous. For example i has uwb (universal weak broad) stability if, under any rule of evolution, it survives sufficiently small heterogeneous invasions.

Relations among stability conditions

Logical implications are indicated by chains of arrows (and by relative vertical position). Conditions stronger than # cannot be satisfied by any EPD and conditions weaker than * are satisfied by EPDs with

all levels of cooperation from 0% to 100%.

Notes to Evolutionary Game Theory

Notes

1. In a mixed strategy, a player assigns a probability to each pure strategy, and chooses which strategy to play using a randomization device. For the Hawk-Dove game, one mixed strategy would assign equal probabilities to playing Hawk or Dove, and decide which to play in a given case by flipping a fair coin.

2. In Nowak and May's model, each individual on the lattice plays the prisoner's dilemma with their eight nearest neighbors. At the end of each game round, an individual compares her score with that of her neighbors. If one of her neighbors earned a higher score, that player will adopt the strategy used by her most successful neighbor (presumably using some kind of randomization process to break ties). If no neighbor earned a higher score, that player will continue using the same strategy for the next round of play. All individuals switch strategies at the same time, and all have the same payoff structure.

3. Of course, Nowak and May were speaking somewhat loosely when they referred to this behavior as "chaotic." Since there are only finitely many states of the population, it must be the case that this dynamical system will eventually settle into a cycle (although it may not repeat itself for a very long time). However, the point is clear enough: in this particular case we are incapable of predicting the state of the model after *N* generations (for a large *N*) without running the model for that length of time. In both of the previous cases, it is easy to predict the future state of the population given its current state.

4. Both agents would clearly do better if both agents elected to cooperate, but the point where both individuals choose cooperate is not a Nash equilibrium: if both agents initially cooperate, the first individual can increase her payoff by choosing to defect (and vice versa).

5. This is a problem only when we consider games other than two-person zero sum games, since all Nash equilibria in these sort of games have equivalent payoffs and are interchangable.

6. One "beauty pageant" game is as follows: a group of subjects is told to choose any number in the interval [0,100]. The person whose choice is closest to half of the mean of the group wins the game. Assuming that the rules of the game and the rationality of the players are common knowledge, the predicted outcome of the game is that all members of the group choose 0. Since 50 is the largest possible winning choice (if each subject chose 100, half of the group mean would be 50), no rational individual would choose a number more than 50. However, since no rational individual would choose a number greater than 50, and all subjects know this, no subject will choose a number greater than 25. In the limit, all players will converge upon 0. Tests with real human subjects (other than game theorists or people who have been exposed to this game before) demonstrate that the modal offer is significantly greater than

zero. If the game is repeated, though, subjects do approach the game theoretic prediction.

7. In the Hawk-Dove game discussed in section 2, the quantities in the payoff matrix represent the change in Darwinian fitness of the two individuals.

8. A more appropriate name would be "Hume's fallacy." Moore's "naturalistic fallacy" discussed in *Principia Ethica* differs significantly from the mistaken inference of an ought-statement from an is-statement. Using the same label for such different fallacies invites confusion.

Teleological Notions in Biology

Teleological terms such as "function" and "design" appear frequently in the biological sciences. Examples of teleological claims include:

- A (biological) function of stotting by antelopes is to communicate to predators that they have been detected.
- Eagles' wings are (naturally) designed for soaring.

Teleological notions were commonly associated with the pre-Darwinian view that the biological realm provides evidence of conscious design by a supernatural creator. Even after creationist viewpoints were rejected by most biologists there remained various grounds for concern about the role of teleology in biology, including whether such terms are:

1. vitalistic (positing some special "life-force");
2. requiring backwards causation (because future outcomes explain present traits);
3. incompatible with mechanistic explanation (because of 1 and 2);
4. mentalistic (attributing the action of mind where there is none);
5. empirically untestable (for all the above reasons).

Opinions divide over whether Darwin's theory of evolution provides a means of eliminating teleology from biology, or whether it provides a naturalistic account of the role of teleological notions in the science. Many contemporary biologists and philosophers of biology believe that teleological notions are a distinctive and ineliminable feature of biological explanations but that it is possible to provide a naturalistic account of their role that avoids the concerns above. Terminological issues sometimes serve to obscure some widely-accepted distinctions.

Teleomentalism

Teleomentalists regard the teleology of psychological intentions, goals, and purposes as the primary model for understanding teleology in biology. Aside from creationism, the most common form of teleomentalist view is that teleological claims in biology are mere metaphor---describing and explaining biological phenomena on the basis of more or less loose comparisons to psychological teleology. Those who hold teleology in biology to be metaphorical in nature typically regard it as eliminable; i.e., they believe that the science of biology would not be essentially altered if all references to teleology were eschewed.

Teleonaturalism

Those who reject teleomentalism typically seek naturalistic truth conditions for teleological claims in biology that do not refer to the intentions, goals, or purposes of psychological agents. Some *teleonaturalists* seek to reduce teleological language to forms of description and explanation that are found in other parts of science. One class of such views defines teleological notions cybernetically and maintains that teleology in biology is appropriate insofar as biological systems are cybernetic systems. Another, more widely-accepted approach treats functional claims in biology as part of the analysis of the capacities of a complex system into various component capacities.

Other forms of teleonaturalism regard the teleological aspects of biology as unique and ineliminable. One class of such views maintains that teleological claims in biology depend on natural values that apply to biological entities (such as what is good for an organism or species). A different approach, that avoids normative notions, is to define biological teleology explicitly in terms of natural selection and the theory of evolution.

Several theorists have argued for the pluralistic idea that biology may incorporate two notions of function, one to explain the presence of traits and the other to explain how those traits contribute to the complex capacities of organisms. Others have argued that these two apparently distinct notions of function can be unified by regarding the target of explanation as the biological fitness of a whole organism. Nonetheless, the mainstream view among philosophers of biology is that natural selection accounts best explain the majority of uses of teleological notions in biology.

Natural Selection Analyses of *Function*

Accounts of biological function which refer to natural selection typically have the form that *a trait's function or functions causally explain the existence or maintenance of that trait in a given population via*

the mechanism of natural selection. Three components of this view can be usefully separated:

1. Functional claims in biology are intended to explain the existence or maintenance of a trait in a given population;
2. Biological functions are causally relevant to the existence or maintenance of traits via the mechanism of natural selection;
3. Functional claims in biology are fully grounded in natural selection and are not derivative of psychological uses of notions such as design, intention, and purpose.

Variations on this account mostly center on the first two points.

1. Some theorists maintain a distinction between the initial spread of a new phenotypic trait in a population from the maintenance of traits in populations.
2. Some theorists adopt an *etiological* or backward-looking approach that analyzes the function of a trait only in terms of those effects of the trait which have in the past contributed to the selection of organisms with that trait. Others adopt a *dispositional* or forward-looking approach that analyzes function in terms of those effects it is disposed to produce that tend to contribute to the present or future maintenance of the trait in a population of organisms.

Function and Design

In the debate about biological teleology, relatively little attention has been paid to the notion of natural design. It is common for authors to slide between claims about function and design as if they accept this principle:

> A trait *T*is naturally designed for *X*if and only if *X*is a biological function of *T*.

Collapsing the notions of design and function in this manner has the advantage that if the notion of biological function is successfully naturalized then so is the notion of natural design.

The biological notion of design seems, however, to imply more than mere usefulness. Female turtles use their flippers to dig nests in sand, and doing so surely accounts for the maintenance of the trait in the population. So, on an etiological account, digging in sand is a function of the flippers. Yet it seems wrong to say that they are designed for that purpose. This suggests that function and design should be analyzed separately. One way to do this is as follows:

> *Trait*T *is naturally designed to do*X means that
> 1. *X* is a biological function of *T* and
> 2. *T* is the result of a process of change of (anatomical or behavioral) structure due to natural selection that has resulted in *T* being more optimal (or better adapted) for *X* than ancestral versions of *T*.

With respect to this analysis, to say that an eagle's wings are designed for soaring is to claim, first, that the ability to soar (as opposed to other kinds of flying) explains why some ancestral eagles had higher reproductive fitness than others and, second, that eagles' wings are better adapted for soaring than were ancestral versions of the wings. This second part is an historical claim that might be checked against the fossil record.

Adaptation, Exaptation and Co-opted Use

The notion of adaptation is controversial among biologists because it suggests the Panglossian belief that this is the best of all possible worlds. However comparative judgments about traits of organisms, e.g., that the traits of present organisms are better at producing some effect than the corresponding traits of ancestral organisms, do not require the Panglossian assumption. This is because the claim that A is more optimal or better adapted than B with respect to some function does not entail that A is optimal or even good with respect to that function.

Gould & Vrba (1982) would deny that sand-digging is a function of turtle flippers and prefer instead to label it an "exaptation". They recommend the use of "function" only when natural selection has "shaped" a trait for some use -- i.e. the trait has undergone some modification in form that makes it more suited to the use. This recommendation, however, seeks to change ordinary biological usage rather than to elucidate it. Because it conflates the notions of design and function, it becomes necessary to mark the distinction between cases of selection with modification (function/design) and cases where a trait of an organism is coopted for a use for which it is not modified (exaptation). Even if the flippers of turtles are not specially modified for burying eggs in sand, the fact that they were so used helps to explain why turtles with flippers were selected over those without. Whether one prefers to call this a function or an exaptation is a terminological issue perhaps to be settled by one's taste for neologisms.

Environmental Ethics

Environmental ethics is the discipline that studies the moral relationship of human beings to, and also the value and moral status of, the environment and its nonhuman contents. This entry covers: (1) the challenge of environmental ethics to the anthropocentrism (i.e., human-centeredness) embedded in traditional western ethical thinking; (2) the early development of the discipline in the 1960s and 1970s; (3) the connection of deep ecology, feminist environmental ethics, and social ecology to politics; (4) the attempt to apply traditional ethical theories, including consequentialism, deontology, and virtue ethics, to support contemporary environmental concerns; and (5) the focus of environmental literature on wilderness, and possible future developments of the discipline.

1. Introduction: The Challenge of Environmental Ethics

Suppose that putting out natural fires, culling feral animals or destroying some individual members of overpopulated indigenous species is necessary for the protection of the integrity of a certain ecosystem. Will these actions be morally permissible or even required? Is it morally acceptable for farmers in non-industrial countries to practise slash and burn techniques to clear areas for agriculture? Consider a mining company which has performed open pit mining in some previously unspoiled area. Does the company have a moral obligation to restore the landform and surface ecology? And what is the value of a humanly restored environment compared with the originally natural environment? It is often said to be morally wrong for human beings to pollute and destroy parts of the natural environment and to consume a huge proportion of the planet's natural resources. If that is wrong, is it simply because a sustainable

environment is essential to (present and future) human well-being? Or is such behaviour also wrong because the natural environment and/or its various contents have certain values in their own right so that these values ought to be respected and protected in any case?

These are among the questions investigated by environmental ethics. Some of them are specific questions faced by individuals in particular circumstances, while others are more global questions faced by groups and communities. Yet others are more abstract questions concerning the value and moral standing of the natural environment and its nonhuman components.

In the literature on environmental ethics the distinction between *instrumental value* and *intrinsic value* (i.e., non-instrumental value) has been of considerable importance. The former is the value of things as *means* to further some other ends, whereas the latter is the value of things as *ends in themselves* regardless of whether they are also useful as means to other ends. For instance, certain fruits have instrumental value for bats who feed on them, since feeding on the fruits is a means to survival for the bats. However, it is not widely agreed that fruits have value as ends in themselves. We can likewise think of a person who teaches others as having instrumental value for those who want to acquire knowledge. Yet, in addition to any such value, it is normally said that a person, as a person, has intrinsic value, i.e., value in his or her own right independently of his or her prospects for serving the ends of others. For another example, a certain wild plant may have instrumental value because it provides the ingredients for some medicine or as an aesthetic object for human observers. But if the plant also has some value in itself independently of its prospects for furthering some other ends such as human health, or the pleasure from aesthetic experience, then the plant also has intrinsic value. Because the intrinsically valuable is that which is good as an end in itself, it is commonly agreed that something's possession of intrinsic value generates a *prima facie* direct moral duty on the part of moral agents to protect it or at least refrain from damaging it.

Many traditional western ethical perspectives, however, are *anthropocentric* or human-centered in that either they assign intrinsic value to human beings alone (i.e., what we might call anthropocentric in an *absolute* sense) or they assign a significantly greater amount of intrinsic value to human beings than to any nonhuman things such that the protection or promotion of human interests or well-being at the expense of nonhuman things turns out to be nearly always justified (i.e., what we might call anthropocentric in a *relative* sense). Aristotle (*Politics*, Bk. 1, Ch. 8) maintains that ‘nature has made all things specifically for the sake of man' and that the value of nonhuman things in nature is merely instrumental. The Bible (*Genesis* 1:27-8) says: “God created man in his own image, in the image of God created he him; male and female created he them. And God blessed them, and God said unto them, Be fruitful, and multiply, and replenish the earth, and subdue it: and have dominion over fish of the sea, and over fowl of the air, and over every living thing that moveth upon the earth.” Thomas Aquinas (*Summa Contra Gentiles*, Bk. 3, Pt 2, Ch 112) argues that because nonhuman animals are ‘ordered to man's use’, he can kill them or use them in any way he wishes without any injustice. Generally, anthropocentric positions find it problematic to articulate what is wrong with the cruel treatment of nonhuman animals, except to the extent that such treatment may lead to bad consequences for human beings. Immanuel Kant (‘Duties to Animals and Spirits’, in *Lectures on Ethics*), for instance, suggested that cruelty towards a dog might encourage a person to develop a character which would be desensitized to cruelty towards

humans. From this standpoint, cruelty towards nonhuman animals would be instrumentally, rather than intrinsically, wrong. Likewise, anthropocentrism often recognizes some non-intrinsic wrongness of anthropogenic (i.e. human-caused) environmental devastation. Such destruction might damage the well-being of human beings (now and in the future), since our well-being is essentially dependent on a sustainable environment (see Passmore 1974, Bookchin 1990, Norton, Hutchins, Stevens, and Maple (eds.) 1995).

When environmental ethics emerged as a new sub-discipline of philosophy in the early 1970s, it did so by posing a challenge to traditional anthropocentrism. In the first place, it questioned the assumed moral superiority of human beings to members of other species on earth. In the second place, it investigated the possibility of rational arguments for assigning intrinsic value to the natural environment and its nonhuman contents.

It should be noted, however, that some theorists working in the field see no need to develop new, non-anthropocentric theories. Instead, they advocate what may be called *enlightened anthropocentrism* (or, perhaps more appropriately called, *prudential anthropocentrism*). Briefly, this is the view that all the moral duties we have towards the environment are derived from our direct duties to its human inhabitants. The practical purpose of environmental ethics, they maintain, is to provide moral grounds for social policies aimed at protecting the earth's environment and remedying environmental degradation. Enlightened anthropocentrism, they argue, is sufficient for that practical purpose, and perhaps even more effective in delivering pragmatic outcomes, in terms of policy-making, than non-anthropocentric theories given the theoretical burden on the latter to provide sound arguments for its more radical view that the nonhuman environment has intrinsic value (cf. Norton 1991, de Shalit 1994, Light and Katz 1996). Furthermore, some prudential anthropocentrists may hold what might be called *cynical anthropocentrism*, which says that we have a higher-level anthropocentric reason to be non-anthropocentric in our day-to-day thinking. The reason for this is that a day-to-day non-anthropocentrist tends to act more benignly towards the nonhuman environment on which human well-being depends. In order to be an effective cynical anthropocentrist, unfortunately, one may need to hide one's cynical anthropocentrism from others and even from oneself.

2. The Early Development of Environmental Ethics

Although nature was the focus of much nineteenth and twentieth century philosophy, contemporary environmental ethics only emerged as an academic discipline in the 1970s. The questioning and rethinking of the relationship of human beings with the natural environment over the last thirty years reflected an already widespread perception in the 1960s that the late twentieth century faced a 'population time bomb' and a serious environmental crisis.

Among the accessible work that drew attention to a sense of crisis was Rachel Carson's *Silent Spring* (1963), which consisted of a number of essays earlier published in the *New Yorker* magazine detailing how pesticides such as DDT, aldrin and deildrin concentrated through the food web. Commercial farming practices aimed at maximizing crop yields and profits, Carson speculated, were capable of impacting

simultaneously on environmental and public health. On the other hand, historian Lynn White jr., in a much-cited essay published in 1967 (White 1967) on the historical roots of the environmental crisis, argued that the main strands of Christian thinking had encouraged the overexploitation of nature by maintaining the superiority of humans over all other forms of life, and by depicting all of nature as created for the use of humans. Nevertheless, White argued that some minority traditions within Christianity (e.g., the views of St. Francis) might provide an antidote to the 'arrogance' of a mainstream tradition steeped in anthropocentrism. Two years later, the Stanford ecologist, Paul Ehrlich, published *The Population Bomb* (1968), warning that the growth of human population threatened the viability of planetary life-support systems. The sense of environmental crisis stimulated by those and other popular works was intensified by NASA's production and wide dissemination of a particularly potent image of earth from space taken at Christmas 1968 and featured in the *Scientific American* in September 1970. Here, plain to see, was a living, shining planet voyaging through space and shared by all of humanity, a precious vessel vulnerable to pollution and to the overuse of its limited capacities. In 1972 a team of researchers at MIT led by Dennis Meadows produced the *Limits to Growth* study, a work that summed up in many ways the emerging concerns of the previous decade and the sense of vulnerability triggered by the view of the earth from space. In §10 of the commentary to the study, the researchers wrote:

> We affirm finally that any deliberate attempt to reach a rational and enduring state of equilibrium by planned measures, rather than by chance or catastrophe, must ultimately be founded on a basic change of values and goals at individual, national and world levels.

The call for a 'basic change of values' in connection to the environment (a call that could be interpreted in terms of either instrumental or intrinsic values) reflected a need for the development of environmental ethics as a new sub-discipline of philosophy.

The new field emerged almost simultaneously in three countries -- the United States, Australia, and Norway. In the first two of these countries, direction and inspiration largely came from the earlier twentieth century American literature of the environment. For instance, the Scottish emigrant John Muir (founder of the Sierra Club and 'father of American conservation') and subsequently the forester Aldo Leopold had advocated an appreciation and conservation of things 'natural, wild and free'. Their concerns were motivated by a combination of ethical and aesthetic responses to nature as well as a rejection of crudely economic approaches to the value of natural objects (a historical survey of the confrontation between Muir's reverentialism and the utilitarian conservationism of Gifford Pinchot (one of the major influences on the development of the US Forest Service) is provided in Norton 1991; also see Cohen 1984 and Nash (ed) 1990). Leopold's *A Sand County Almanac* (1949), in particular, advocated the adoption of a 'land ethic':

> That land is a community is the basic concept of ecology, but that land is to be loved and respected is an extension of ethics. (vii-ix)
> A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise. (224-5)

However, Leopold himself provided no systematic ethical theory or framework to support these ethical

ideas concerning the environment. His views therefore presented a challenge and opportunity for moral theorists: could some ethical theory be devised to justify the injunction to preserve the integrity, stability and beauty of the biosphere?

The land ethic sketched by Leopold, attempting to extend our moral concern to cover the natural environment and its nonhuman contents, was drawn on explicitly by the Australian philosopher Richard Routley (later Sylvan). According to Routley (1973 (cf. Routley and Routley 1980)), the anthropocentrism imbedded in what he called the ‘dominant western view’, or ‘the western superethic’, is in effect ‘human chauvinism’. This view, he argued, is just another form of class chauvinism, which is simply based on blind class ‘loyalty’ or prejudice, and unjustifiably discriminates against those outside the privileged class. Furthermore, in his ‘last man’ (and ‘last people’) arguments, Routley asked us to imagine the hypothetical situation in which the last person, surviving a world catastrophe, acted to ensure the elimination of all other living things and the destruction of all the landscapes after his demise. From the human-chauvinistic (or absolutely anthropocentric) perspective, the last person would do nothing morally wrong, since his or her destructive act in question would not cause any damage to the interest and well-being of humans, who would have by then disappeared. Nevertheless, Routley believed that that the imagined last act would be morally wrong. An explanation for this judgment, he suggested, is that those nonhuman objects in the environment, whose destruction is ensured by the last person, have intrinsic value, a kind of value independent of their usefulness for humans. From his critique, Routley concluded that the main approaches in traditional western moral thinking were unable to allow the recognition that natural things have intrinsic value, and that the tradition required overhaul of a significant kind.

Leopold's idea that the ‘land’ as a whole is an object of our moral concern also stimulated writers to argue for certain moral obligations toward ecological wholes, such as species, communities, and ecosystems, not just their individual constituents. American environmental philosopher Holmes Rolston III (1975), for instance, argued that species protection was a moral duty. It would be wrong, Rolston maintained, to eliminate a rare butterfly species simply to increase the monetary value of specimens already held by collectors. Like Routley's ‘last man’ arguments, Rolston's example is meant to draw attention to a kind of action that seems morally dubious and yet is not clearly ruled out or condemned by traditional anthropocentric ethical views. Species, Rolston went on to argue, are intrinsically valuable and are usually more valuable than individual specimens, since the loss of a species is a loss of genetic possibilities and the deliberate destruction of a species would show disrespect for the very biological processes which make possible the emergence of individual living things (also see Rolston 1989, Ch 10).

Meanwhile, the work of Christopher Stone (a professor of law at the University of Southern California) had become widely discussed. Stone (1972) proposed that trees and other natural objects should have at least the same standing in law as corporations. This suggestion was inspired by a particular case in which the Sierra Club had mounted a challenge against the permit granted by the U.S.Forest Service to Walt Disney Enterprises for surveys preparatory to the development of the Mineral King Valley, which was at the time a relatively remote game refuge, but not designated as a national park or protected wilderness area. The Disney proposal was to develop a major resort complex serving 14000 visitors daily to be accessed by a purpose-built highway through Sequoia National Park. The Sierra Club,as a body with a

general concern for conservation, challenged the development on the grounds that the valley should be kept in its original state for its own sake.

Stone reasoned that if trees, forests and mountains could be given standing in law then they could be represented in their own right in the courts by groups such as the Sierra Club. Moreover, like any other *legal person*, these natural things could become beneficiaries of compensation if it could be shown that they had suffered compensatable injury through human activity. When the case went to the U.S. Supreme Court, it was determined by a narrow majority that the Sierra Club did not even meet the condition for bringing a case to court, for the Club was unable and unwilling to prove the likelihood of injury to the interest of the Club or its members. In a dissenting minority judgment, however, justices Douglas, Blackmun and Brennan mentioned Stone's argument: his proposal to give legal standing to natural things, they said, would allow conservation interests, community needs and business interests to be represented, debated and settled in court.

Reacting to Stone's proposal, Joel Feinberg (1974) raised a serious problem. Only items that have interests, Feinberg argued, can be regarded as having legal standing and, likewise, moral standing. For it is interests which are capable of being represented in legal proceedings and moral debates. This same point would also seem to apply to political debates. For instance, the movement for ‘animal liberation’, which also emerged strongly in the 1970s, can be thought of as a political movement aimed at representing the previously neglected interests of some animals (see Regan and Singer (eds.) 1976, and Clark 1977). Granted that some animals have interests that can be represented in this way, would it also make sense to speak of trees, forests, rivers, barnacles, or termites as having interests of a morally relevant kind? This issue was hotly contested in the years that followed. Meanwhile, John Passmore (1974) argued, like White, that the Judeo-Christian tradition of thought about nature, despite being predominantly ‘despotic’, contained resources for regarding humans as ‘stewards’ or ‘perfectors’ of God's creation. Skeptical of the prospects for any radically new ethic, Passmore cautioned that traditions of thought could not be abruptly overhauled. Any change in attitudes to our natural surroundings which stood the chance of widespread acceptance, he argued, would have to resonate and have some continuities with the very tradition which had legitimized our destructive practices. In sum, then, Leopold's land ethic, the historical analyses of White and Passmore, the pioneering work of Routley, Stone and Rolston, and the warnings of scientists, had by the late 1970s focused the attention of philosophers and political theorists firmly on the environment.

The confluence of ethical, political and legal debates about the environment, the emergence of philosophies to underpin animal rights activism and the puzzles over whether an environmental ethic would be something new rather than a modification or extension of existing ethical theories were reflected in wider social and political movements. The rise of environmental or ‘green’ parties in Europe in the 1980s was accompanied by almost immediate schisms between groups known as ‘realists’ versus ‘fundamentalists’ (see Dobson 1992). The ‘realists’ stood for reform environmentalism, working with business and government to soften the impact of pollution and resource depletion especially on fragile ecosystems or endangered species. The ‘fundies’ argued for radical change, the setting of stringent new priorities, and even the overthrow of capitalism and liberal individualism, which were taken as the major ideological causes of anthropogenic environmental devastation. Underlying these disagreements was the

distinction between 'shallow' and 'deep' environmental movements, a distinction introduced in the early 1970s by another major influence on contemporary environmental ethics, the Norwegian philosopher and climber Arne Næss. Since the work of Næss has been significant in environmental politics, the discussion of his position is given in a separate section below.

3. Environmental Ethics and Politics

3.1 Deep Ecology

'Deep ecology' was born in Scandinavia, the result of discussions between Næss and his colleagues Sigmund Kvaløy and Nils Faarlund (see Næss 1973 and 1989; also see Witoszek and Brennan (eds.) 1999 for a historical survey and commentary on the development of deep ecology). All three shared a passion for the great mountains. On a visit to the Himalayas, they became impressed with aspects of 'Sherpa culture' particularly when they found that their Sherpa guides regarded certain mountains as sacred and accordingly would not venture onto them. Næss decided to formulate a position which extended the reverence he and the Sherpas felt for mountains to other natural things in general.

The 'shallow ecology movement', as Næss (1973) calls it, is the 'fight against pollution and resource depletion', the central objective of which is 'the health and affluence of people in the developed countries.' The 'deep ecology movement', in contrast, endorses 'biospheric egalitarianism', the view that all living things are alike in having value in their own right, independent of their usefulness to human purposes. The deep ecologist respects this intrinsic value, taking care, for example, when walking on the mountainside not to cause unnecessary damage to the plants. Furthermore, deep ecology also endorses what Næss calls the 'relational, total-field image', understanding organisms (human or otherwise) as 'knots' in the biospherical net, the identities of which are defined in terms of their ecological relations to each other. Næss maintains that the 'deep' satisfaction that we receive from close partnership with other forms of life in nature contributes significantly to our life quality. As developed by Næss and others, the position also came to focus on the possibility of the 'identification' of the human ego with nature. The idea is briefly that by identifying with nature we can enlarge the boundaries of the self. Self-respect thus extends beyond the boundaries of my skin. My larger -- ecological -- Self (the capital 'S' emphasizes that I am an individual some of whose parts are found outside of my skin), according to Næss, deserves respect as well. And to respect and to care for myself is also to respect and to care for the natural environment with which I identify myself. 'Self-realization', in other words, is the reconnection of the shriveled human individual with the wider natural environment. One clear historical antecedent to this view is the romanticism of Jean-Jacques Rousseau as expressed in his last work, the *Reveries of the Solitary Walker*, though Næss himself cites Spinoza as the major historic inspiration of his deep ecology.

When Næss's view crossed the Atlantic, it was sometimes merged with ideas emerging from Leopold's land ethic (see Devall and Sessions 1985; also see Sessions (ed) 1995). But Næss -- wary of the apparent totalitarian political implications of Leopold's position that individual interests and well-being should be subordinated to the holistic good of the earth's biotic community (see section 4 below) -- has always taken care to distance himself from advocating any sort of 'land ethic'. Some later critics have argued

that Næss's deep ecology is no more than an extended social-democratic version of utilitarianism, which counts human interests in the same calculation alongside the ‘interests’ of all natural things (e.g., trees, wolves, bears, rivers, forests and mountains) in the natural environment (see Witoszek 1997). However, Næss failed to explain in any detail how to make sense of the idea that oysters or barnacles, termites or bacteria could have interests of any morally relevant sort at all. Without an account of this, Næss 's early ‘biospheric egalitarianism’ - that all living things whatsoever had a similar right to live and flourish - was an indeterminate principle. It also remains unclear how rivers, mountains and forests can be regarded as possessors of any kind of interests at all. This is an issue on which Næss has always remained elusive.

Biospheric egalitarianism was modified in the 1980s to the weaker claim that the flourishing of both human and non-human life have value in themselves. At the same time, Næss declared that his own favoured ecological philosophy -- ’Ecosophy T’, as he called it after his Tvergastein mountain cabin-- was only one of several possible foundations for an environmental ethic. Deep ecology ceased to be a specific doctrine, but instead became a ‘platform’, of eight points, on which Næss hoped all deep green thinkers could agree. The platform was conceived as establishing a middle ground, between underlying philosophical orientations, whether Christian, Buddhist, Taoist, process philosophy, or whatever, and the practical principles determining action in specific situations. Thus the deep ecological movement became explicitly pluralist (see Brennan 1999; c.f. Light 1996).

While Næss's Ecosophy T sees human Self-realization as a solution to the environmental crises resulting from human selfishness and exploitation of nature, some of the American and Australian followers of the deep ecology platform further argue that the expansion of the human self to include nonhuman nature is supported by the Copenhagen interpretation of quantum theory, which is said to have dissolved the boundaries between the observer and the observed (see Fox 1984, 1990, and Devall and Sessions 1985; cf. Callicott 1985). These developments of deep ecology were, however, criticized by some feminist theorists, who argued that the theory of the expanded self is in effect a disguised form of human -- indeed masculine -- egoism, unable to give nature its due respect as a genuine ‘other’ independent of human interest and well-being (see Plumwood 1993, Ch. 7, 1999, and Warren 1999). Meanwhile, some third-world critics have accused deep ecology of being elitist in its attempts to preserve wilderness experiences for only a select group of economically and socio-politically well-off people. The Indian writer Ramachandra Guha (1989, 1999) for instance, depicts the activities of many western-based conservation groups as a new form of cultural imperialism, aimed at securing converts to conservationism (cf. Bookchin 1987 and Brennan 1998a). ‘Green missionaries’, as Guha calls them, represent a movement aimed at further dispossessing the world's poor and indigenous people. “Putting deep ecology in its place,” he writes, “is to recognize that the trends it derides as "shallow" ecology might in fact be varieties of environmentalism that are more apposite, more representative and more popular in the countries of the South.” Although Næss himself repudiates suggestions that deep ecology is committed to any imperialism (see Witoszek and Brennan (eds.) 1999, Ch. 36-7 and 41), Guha's criticism raises important questions about the application of deep ecological principles in different social, economic and cultural contexts. In other critiques, deep ecology has been portrayed as having an inconsistent utopian vision (see Anker and Witoszek 1998).

3.2 Feminism and the Environment

Broadly speaking, a ‘feminist issue’ is any issue that contributes in some way to understanding the oppression of women. Feminist theories attempt to analyze women's oppression, its causes and consequences, and suggest strategies and directions for women's liberation. By the mid 1970s, feminist writers had raised the issue of whether patriarchal modes of thinking encouraged not only widespread inferiorizing and colonizing of women, but also of coloured people, animals and nature. Sheila Collins (1974), for instance, argued that male-dominated culture or patriarchy is supported by four interlocking pillars: sexism, racism, class exploitation, and ecological destruction.

Emphasizing the importance of feminism to the environmental movement and various other liberation movements, some writers, such as Ynestra King (1989a and 1989b), argue that the domination of women by men is the original form of domination in human society, from which all other hierarchies -- of rank, class, and political power -- flow. For instance, human domination of nature, it has been argued, is a manifestation and extension of the oppression of women, in that it is the result of associating nature with the female, which had been already inferiorized and oppressed by the male-dominating human culture. But within the plurality of feminist positions, other writers, such as Val Plumwood (1993), understand the oppression of women as only one of the many parallel forms of oppressions sharing and supported by a common structure, in which one party (the colonizer) uses a number of conceptual and rhetorical devices to privilege its interests over that of the other party (the colonized). It is argued that male-centered (androcentric) and human-centered (anthropocentric) thinking have some common characteristics, such as ‘dualism’ and the ‘logic of domination’, which are also manifested in the oppressions of many other social groups, and that in being facilitated by a common ideological structure, diverse forms of oppression often mutually-reinforce each other (Warren 1987, 1990, 1994, Cheney 1989, and Plumwood 1993). A central target of feminist analysis are those patterns of ‘dualism’ that lie deep in patriarchal thought. Examples are polar opposites, such as male/female, human/nonhuman, culture/nature, mind/body, reason/emotion, freedom/necessity. These dualisms are not just descriptive dichotomies, according to many feminists, but involve a prescriptive privileging of one side of the opposed items over the other, which is often rationalized by alleged ‘discovery’ of some qualities of the dominating groups that are meant to justify the domination that the privileged wields over the subjugated. For instance, the male may be said to excel in rationality over the emotional female; the active Cartesian mind, being free from physical constrains, may be seen as superior to the mechanical passive body; the civilized and progressive human culture may be deemed superior to the primitive nonhuman nature.

The insight of feminism, however, is not just that the dominating party often falsely sees the dominated party as lacking (or possessing) the allegedly superior (or inferior) qualities. More important, according to feminist analyses, the very premise of prescriptive dualism -- the valuing of attributes of one polarized side and the devaluing of those of the other, the idea that domination and oppression can be justified by appealing to attributes like masculinity, rationality, being civilized or developed, etc. -- is itself problematic.

Feminism represents a radical challenge for environmental thinking, politics, and traditional social

ethical perspectives. It promises to link environmental questions with wider social problems concerning various kinds of discrimination and exploitation, and fundamental investigations of human psychology. However, whether there are conceptual or merely contingent connections among the different forms of oppression and liberation remains a contested issue (see Green 1994). The term ‘ecofeminism’ (first coined by Françoise d'Eaubonne in 1974) is now generally applied to any view that combines environmental advocacy with feminist analysis. However, because of the varieties of, and disagreements among, feminist theories, the label may be too wide to be informative. Some feminist writers on environmental issues are wary of calling themselves ‘ecofeminists’.

3.3 Social Ecology

Apart from feminist-environmentalist theories and Næss's deep ecology, Murray Bookchin's ‘social ecology’ has also claimed to be radical, subversive, or countercultural (see Bookchin 1980, 1987, 1990).

One major influence on Bookchin's social ecology is the Frankfurt School of ‘critical theory’. Classical Marxists regarded Nature as a resource to be transformed by human labour and utilized. Members of the Frankfurt School such as Max Horkheimer and Theodore Adorno interpret Marx himself as representative of the problem of human alienation from nature. At the root of this alienation, they argue, is a narrow positivist conception of rationality -- which sees rationality as an instrument for pursuing power, technological control and progress, and takes observation, measurement and the application of purely quantitative methods to be capable of solving all problems. This conception, Horkheimer and Adorno (1969) argue, requires revision. Their project is to replace the narrow positivistic model of rationality with the so-called ‘Romantic’ values of the aesthetic, moral, sensual and expressive aspects of human nature, and bring these into harmony with our rational faculties. The oppression of what they call ‘outer nature’ (i.e., the natural environment) through science and technology, they argue, is bought at a very high price: the project of domination requires the suppression of our ‘inner nature’, the world of manifold needs and longings at the center of human life and its vulnerability (also see Eckersley 1992 and Vogel 1996, for a review of the Frankfurt School's thinking about nature).

Bookchin's version of critical theory takes the ‘outer’ physical world as constituting what he calls ‘first nature’, from which culture or ‘second nature’ has evolved. Environmentalism, on his view, is a social movement, and the problems it confronts are social problems. While Bookchin is prepared, like Horkheimer and Adorno, to regard (first) nature as an aesthetic and sensuous marvel, he regards our intervention in it as necessary. He suggests that we can choose to put ourselves at the service of natural evolution, to help maintain complexity and diversity, diminish suffering and reduce pollution. In this way, we can also to some extent overcome the kind of alienation that so worried the Frankfurt School. Bookchin's social ecology recommends that we use our gifts of sociability, communication and intelligence as if we were ‘nature rendered conscious’, instead of turning them against the very source and origin from which such gifts derive. Oppression of nature should be replaced by a richer form of life devoted to nature's preservation.

Deep ecology, feminism, and social ecology have had a considerable impact on the development of

political positions in regard to the environment. Feminist analyses have often been welcomed for the psychological insight they bring to several social, moral and political problems. There is, however, considerable unease about the implications of critical theory, social ecology and some varieties of deep ecology. Some recent writers have argued, for example, that critical theory is bound to be ethically anthropocentric, with nature as no more than a ‘social construction’ whose value ultimately depends on human determinations (see Vogel 1996). Others have argued that the demands of ‘deep’ green theorists and activists cannot be accommodated within contemporary theories of liberal politics and social justice (see Ferry 1998). A further suggestion is that there is a need to reassess traditional theories such as virtue ethics, which has its origins in ancient Greek philosophy (see the following section) within the context of a form of stewardship similar to that earlier endorsed by Passmore (see Barry 1999). If this last claim is correct, then the radical activist need not, after all, look for philosophical support in radical, or countercultural, theories of the sort deep ecology, feminism and social ecology claim to be.

4. Traditional Ethical Theories and Contemporary Environment Ethics

Although environmental ethicists often try to distance themselves from the anthropocentrism embedded in traditional ethical views (Passmore 1974, Norton 1991 are exceptions), they also quite often draw their theoretical resources from traditional ethical systems and theories. Consider the following two basic moral questions: (1) What kinds of thing are intrinsically valuable, good or bad? (2) What makes an action right or wrong?

Consequentialist ethical theories consider intrinsic ‘value’/‘disvalue’ or ‘goodness’/‘badness’ to be more fundamental moral notions than ‘rightness’/‘wrongness’, and maintain that whether an action is right/wrong is determined by whether its consequences are good/bad. From this perspective, answers to question (2) are informed by answers to question (1). For instance, utilitarianism, a paradigm case of consequentialism, regards pleasure (or, more broadly construed, the satisfaction of interest, desire, and/or preference) as the only intrinsic value in the world, whereas pain (or the frustration of desire, interest, and/or preference) the only intrinsic disvalue, and maintains that right actions are those that would produce the greatest balance of pleasure over pain.

As the utilitarian focus is the balance of pleasure and pain as such, the question of to whom a pleasure or pain belongs is irrelevant to the calculation and assessment of the rightness or wrongness of actions. Hence, the eighteenth century utilitarian Jeremy Bentham (1789), and now Peter Singer (1993), have argued that the interests of all the sentient beings (i.e., beings who are capable of experiencing pleasure or pain) -- including nonhuman ones -- affected by an action should be taken equally into consideration in assessing the action. Furthermore, rather like Routley (see section 2 above), Singer argues that the anthropocentric privileging of members of the species *Homo sapiens* is arbitrary, and that it is a kind of ‘speciesism’ as unjustifiable as sexism and racism. Singer regards the animal liberation movement as comparable to the liberation movements of women and people of colour. Unlike the environmental philosophers who attribute intrinsic value to the natural environment and its inhabitants, Singer and

utilitarians in general attribute intrinsic value to the experience of pleasure or interest satisfaction as such, not to the beings who have the experience. Similarly, for the utilitarian, non-sentient objects in the environment such as plant species, rivers, mountains, and landscapes, all of which are the objects of moral concern for environmentalists, are of no intrinsic but at most instrumental value to the satisfaction of sentient beings (see Singer 1993, Ch. 10). Furthermore, because right actions, for the utilitarian, are those that maximize the overall balance of interest satisfaction over frustration, practices such as whale-hunting and the killing of an elephant for ivory, which cause suffering to nonhuman animals, might turn out to be right after all: such practices might produce considerable amounts of interest-satisfaction for human beings, which, on the utilitarian calculation, outweigh the nonhuman interest-frustration involved. As the result of all the above considerations, it is unclear to what extent a utilitarian ethic can also be an environmental ethic. This point may not so readily apply to a wider consequentialist approach, which attributes intrinsic value not only to pleasure or satisfaction, but also to various objects and processes in the natural environment.

Deontological ethical theories, in contrast, maintain that whether an action is right or wrong is for the most part independent of whether its consequences are good or bad. From the deontologist perspective, there are several distinct moral rules or duties (e.g., ‘not to kill or otherwise harm the innocent’, ‘not to lie’, ‘to respect the rights of others’, ‘to keep promises’), the observance/violation of which is intrinsically right/wrong; i.e., right/wrong in itself regardless of consequences. When asked to justify an alleged moral rule, duty or its corresponding right, deontologists may appeal to the intrinsic value of those beings to whom it applies. For instance, ‘animal rights’ advocate Tom Regan (1983) argues that those animals with intrinsic value (or what he calls ‘inherent value’) have the moral right to respectful treatment, which then generates a general moral duty on our part not to treat them as mere means to other ends. We have, in particular, a *prima facie* moral duty not to harm them. Regan maintains that certain practices (such as sport or commercial hunting, and experimentation on animals) violate the moral right of intrinsically valuable animals to respectful treatment. Such practices, he argues, are intrinsically wrong regardless of whether or not some better consequences ever flow from them. Exactly which animals have intrinsic value and therefore the moral right to respectful treatment? Regan's answer is: those that meet the criterion of being the ‘subject-of-a-life’. To be such a subject is a sufficient (though not necessary) condition for having intrinsic value, and to be a subject-of-a-life involves, among other things, having sense-perceptions, beliefs, desires, motives, memory, a sense of the future, and a psychological identity over time.

Some authors have extended concern for individual well-being further, arguing for the intrinsic value of organisms achieving their own good, whether those organisms are capable of consciousness or not. Paul Taylor's version of this view (1981 and 1986), which we might call *biocentrism*, is a deontological example. He argues that each individual living thing in nature -- whether it is an animal, a plant, or a micro-organism -- is a ‘teleological-center-of-life’ having a good or well-being of its own which can be enhanced or damaged, and that all individuals who are teleological-centers-of life have equal intrinsic value (or what he calls ‘inherent worth’) which entitles them to moral respect. Furthermore, Taylor maintains that the intrinsic value of wild living things generates a *prima facie* moral duty on our part to preserve or promote their goods as ends in themselves, and that any practices which treat those beings as mere means and thus display a lack of respect for them are intrinsically wrong. Unlike Taylor's

egalitarian and deontological biocentrism, Robin Attfield (1987) argues for a hierarchical view that while all beings having a good of their own have intrinsic value, some of them (e.g., persons) have intrinsic value to a greater extent. Attfield also endorses a form of consequentialism which takes into consideration, and attempts to balance, the many and possibly conflicting goods of different living things (also see Varner 1998 for a more recent defense of what he calls *biocentric individualism* with affinities to both consequentialist and deontological approaches). However, some critics have pointed out that the notion of biological good or well-being is only descriptive not prescriptive (see Williams 1992 and O'Neill 1993, Ch. 2). For instance, the fact that HIV has a good of its own does not mean that we ought to assign any positive moral weight to the realization of that good.

Note that the ethics of animal liberation or animal rights and biocentrism are both *individualistic* in that their various moral concerns are directed towards individuals only -- not ecological wholes such as species, populations, biotic communities, and ecosystems. None of these is sentient, a subject-of-a-life, or a teleological-center-of-life, but the preservation of these collective entities is a major concern for many environmentalists. Moreover, the goals of animal liberationists, such as the reduction of animal suffering and death, may conflict with the goals of environmentalists. For example, the preservation of the integrity of an ecosystem may require the culling of feral animals or of some indigenous populations that threaten to destroy fragile habitats. So there are disputes about whether the ethics of animal liberation is a proper branch of environmental ethics (see Callicott 1980, 1988, Sagoff 1984, Jamieson 1998, Crisp 1998 and Varner 2000).

Criticizing the individualistic approach in general for failing to accommodate conservation concerns for ecological wholes, J. Baird Callicott (1980) has advocated a version of land-ethical *holism* which takes Leopold's statement “A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise” to be the supreme deontological principle. In this theory, the earth's biotic community per se is the sole locus of intrinsic value, whereas the value of its individual members is merely instrumental and dependent on their contribution to the ‘integrity, stability, and beauty’ of the larger community. A straightforward implication of this version of the land ethic is that an individual member of the biotic community ought to be sacrificed whenever that is needed for the protection of the holistic good of the community. For instance, Callicott maintains that if culling a white-tailed deer is necessary for the protection of the holistic biotic good, then it is a land-ethical requirement to do so. But, to be consistent, the same point also applies to human individuals because they are also members of the biotic community. Not surprisingly, the misanthropy implied by Callicott's land-ethical holism has been widely criticized and regarded as a reductio of the position (see Aiken (1984), Kheel (1985), Ferré (1996), and Shrader-Frechette (1996)). Tom Regan (1983, p.362), for example, has condemned the holistic land ethic's disregard of the rights of the individual as ‘environmental fascism’. Under the pressure from the charge of ecofascism and misanthropy, Callicott (1989 Ch. 5, and 1999, Ch. 4) has later revised his position and now maintains that the biotic community (indeed, any community to which we belong) as well as its individual members (indeed, any individual who shares with us membership in some common community) all have intrinsic value. The controversy surrounding Callicott's original position, however, has inspired efforts in environment ethics to investigate possibilities of attributing intrinsic value to ecological wholes, not just their individual constituent parts (see Lo 2001 for an overview and critique of Callicott's changing position over the last two decades; also

see Ouderkirk and Hill (eds.) 2002 for debates between Callicott and others concerning the metaethical and metaphysical foundations for the land ethic and also its historical antecedents).

Individual natural entities (whether sentient or not, living or not), Andrew Brennan (1984) argues, are not designed by anyone to fulfill any purpose and therefore lack ‘intrinsic function’ (i.e., the function of a thing that constitutes part of its essence or identity conditions). This, he proposes, is a reason for thinking that individual natural entities should not be treated as mere instruments, and thus a reason for assigning them intrinsic value. Furthermore, he argues that the same moral point applies to the case of natural ecosystems, to the extent that they lack intrinsic function. In the light of Brennan's proposal, Eric Katz (1991 and 1997) argues that all natural entities, whether individuals or wholes, have intrinsic value in virtue of their ontological independence from human purpose, activity, and interest, and maintains the deontological principle that nature as a whole is an ‘autonomous subject’ which deserves moral respect and must not be treated as a mere means to human ends. Carrying the project of attributing intrinsic value to nature to its ultimate form, Robert Elliot (1997) argues that naturalness itself is a property in virtue of possessing which all natural things, events, and states of affairs, attain intrinsic value. Furthermore, Elliot argues that even a consequentialist, who in principle allows the possibility of trading off intrinsic value from naturalness for intrinsic value from other sources, could no longer justify such kind of trade-off in reality. This is because the reduction of intrinsic value due to the depletion of naturalness on earth, according to him, has reached such a level that any further reduction of it could not be compensated by any amount of intrinsic value generated in other ways, no matter how great it is.

As the notion of ‘natural’ is understood in terms of the lack of human contrivance and is often opposed to the notion of ‘artifactual’, one much contested issue is about the value of those parts of nature that have been interfered with by human artifice -- for instance, previously degraded natural environments which have been humanly restored. Based on the premise that the properties of being naturally evolved and having a natural continuity with the remote past are ‘value adding’ (i.e., adding intrinsic value to those things which possess those two properties), Elliot argues that even a perfectly restored environment would necessarily lack those two value-adding properties and therefore be less valuable than the originally undegraded natural environment. Katz, on the other hand, argues that a restored nature is really just an artifact designed and created for the satisfaction of human ends, and that the value of restored environments is merely instrumental. However, some critics have pointed out that advocates of moral dualism between the natural and the artifactual run the risk of diminishing the value of human life and culture, and fail to recognize that the natural environments interfered with by humans may still have morally relevant qualities other than pure naturalness (see Lo 1999). Two other issues central to this debate are that the key concept ‘natural’ seems ambiguous in many different ways (see Hume 1751, App. 3, and Brennan 1988, Ch. 6, Elliot 1997, Ch. 4), and that those who argue that human interference reduces the intrinsic value of nature seem to have simply assumed the crucial premise that naturalness is a source of intrinsic value. Some thinkers maintain that the natural, or the ‘wild’ construed as that which ‘is not humanized’ (Hettinger and Throop 1999, p. 12) or to some degree ‘not under human control’ (*ibid*., p. 13) is intrinsically valuable. Yet, as Bernard Williams points out (Williams 1992), we may, paradoxically, need to use our technological powers to retain a sense of something not being in our power. The retention of wild areas may thus involve planetary and ecological management to maintain, or even ‘imprison’ such areas (Birch 1990), raising a question over the extent to which national parks and

wilderness areas are free from our control. An important message underlying the debate, perhaps, is that even if ecological restoration is achievable, it might have been better to have left nature intact in the first place.

As an alternative to consequentialism and deontology both of which consider ‘thin’ concepts such as ‘goodness’ and ‘rightness’ as essential to morality, virtue ethics proposes to understand morality -- and assess the ethical quality of actions -- in terms of ‘thick’ concepts such as ‘kindness’, ‘honesty’, ‘sincerity’ and ‘justice’. As virtue ethics speaks quite a different language from the other two kinds of ethical theory, its theoretical focus is not so much on what kinds of things are good/bad, or what makes an action right/wrong. One question central to virtue ethics is what the moral reasons are for acting one way or another. For instance, from the perspective of virtue ethics, kindness and loyalty would be moral reasons for helping a friend in hardship. These are quite different from the deontologist's reason (that the action is demanded by a moral rule) or the consequentialist reason (that the action will lead to a better over-all balance of good over evil in the world). From the perspective of virtue ethics, the motivation and justification of actions are both inseparable from the character traits of the acting agent. Furthermore, unlike deontology or consequentialism the moral focus of which is other people or states of the world, one central issue for virtue ethics is how to live a flourishing human life, this being a central concern of the moral agent himself or herself. ‘Living virtuously’ is Aristotle's recipe for flourishing. Versions of virtue ethics advocating virtues such as ‘benevolence’, ‘piety’, ‘filiality’, and ‘courage’, have also been held by thinkers in the Chinese Confucian tradition. The connection between morality and psychology is another core subject of investigation for virtue ethics. It is sometimes suggested that human virtues, which constitute an important aspect of a flourishing human life, must be compatible with human needs and desires, and perhaps also sensitive to individual affection and temperaments. As its central focus is human flourishing as such, virtue ethics may seem unavoidably anthropocentric and unable to support a genuine moral concern for the nonhuman environment. But just as Aristotle has argued that a flourishing human life requires friendships and one can have genuine friendships only if one genuinely values, loves, respects, and cares for one's friends for their own sake, not merely for the benefits that they may bring to oneself, some have argued that a flourishing human life requires the moral capacities to value, love, respect, and care for the nonhuman natural world as an end in itself (see O'Neill 1992, O'Neill 1993, Barry 1999).

5. Wilderness and Developing Trends

Despite the variety of positions in environmental ethics developed over the last thirty years, they have largely focused on issues concerned with ‘wilderness’ and the reasons for its preservation. Little attention was paid to the built environment, although this is the one in which most people spend most of their time. In post-war Britain, for example, cheaply constructed new housing developments were often poor replacements for traditional communities. They have been associated with lower amounts of social interaction and increased crime compared with the earlier situation. The destruction of highly functional high-density traditional housing, indeed, might be compared with the destruction of highly diverse ecosystems and biotic communities. Likewise, the loss of the world's huge diversity of natural languages has been mourned by many, not just professionals with an interest in linguistics. Urban and linguistic

environments are just two of the many ‘places’ inhabited by humans. Perhaps the philosophical literature on the natural environment can be extended to cover environments of those other sorts as well (see King 2000, Light forthcoming, and Palmer forthcoming, for such an attempt).

The importance of wilderness experience to the human psyche has been emphasized by many environmental philosophers. Næss, for instance, urges us to ensure we spend time dwelling in situations of intrinsic value, whereas Rolston meditates in the wilderness on the importance of ‘re-creation’ afforded by experiences of wild nature. However, lifestyles in which enthusiasms for mountaineering, nature rambles and woodland meditations can be indulged demand a standard of living that is far beyond the dreams of most of the world's population. Hugh Stretton (1976) has characterized those environmentalists ‘driven chiefly by love of the wilderness’ as ‘natural aristocrats’. Mass access to wild places would likely destroy the very values held in high esteem by Stretton's ‘aristocrats’. So a question hangs over how to reconcile limiting the access of people to wilderness while maintaining the individual freedoms central to liberal democracies. Furthermore, lovers of wilderness sometimes consider the high human populations in some developing countries as a key problem underlying the environmental crisis. Rolston (1996), for instance, claims that humans are a kind of planetary ‘cancer’. He maintains that while “feeding people always seems humane, ... when we face up to what is really going on, by just feeding people, without attention to the larger social results, we could be feeding a kind of cancer.” This remark is meant to justify the view that saving nature should, in some circumstances, have a higher priority than feeding people. But such a view has been criticized for seeming to reveal a degree of misanthropy, directed at those human beings least able to protect and defend themselves (see Attfield 1998, Brennan 1998a). Guha's worries about the elitist and ‘missionary’ tendencies of some kinds of ‘deep’ green environmentalism in certain rich western countries can be quite readily extended to theorists such as Rolston. Can such elitism of the environmental sort ever be democratized? How can the psychically-reviving power of the wild become available to those living in the slums of Calcutta or Sao Paolo? These questions so far lack convincing answers.

The economic conditions which support the kind of enjoyment of wilderness by Stretton's ‘aristocrats’, and more generally the lifestyles of many people in the affluent countries, seem implicated in the destruction and pollution which has provoked the environmental turn in the first place. For those in the rich countries, for instance, engaging in outdoor recreations usually involves the motor car. Car dependency, however, is at the heart of many environmental problems, a key factor in urban pollution, while at the same time central to the economic and military activities of many nations and corporations, for example those activities associated with securing and exploiting oil resources. A range of new moral and political problems may open up for us. These include the problems of the environmental cost of tourist access to wilderness areas, and the fair ways in which limited access could be arranged to areas of natural diversity and beauty. International problems concern the exploitation of people in the world's economically poor nations as an aspect of an economic system supporting the lifestyles of the wealthy, and also oppression and war associated with securing oil and other resources of significance to the industrialized countries. In an increasingly crowded world, the answers to such problems will not be obvious and may require academic co-operation between philosophers and workers in other disciplines in an attempt to solve them.

Connections between environmental destruction, unequal resource consumption, poverty and the global economic order have been discussed by political scientists, development theorists, geographers and economists as well as by philosophers. Links between economics and environmental ethics are particularly well established. Work by Mark Sagoff (1988), for instance, has played a major part in bringing the two fields together (also see Shrader-Frechette 1987, O'Neill 1993, and Brennan 1995). Sagoff argued forcefully against confusing values with matters of preference (even considered preference), and claimed that ¡V as citizens rather than consumers ¡V people are concerned about values that cannot plausibly be monetized. The potentially misleading appeal to economic reason used to justify the expansion of the corporate sector has also come under critical scrutiny (see Korten 1999, Ch. 2, Plumwood (formerly V. Routley) 2002). These critiques do not aim to eliminate economics from environmental thinking; rather, they resist any reductive, and strongly anthropocentric, tendency to believe that all social problems are 'fundamentally' or 'essentially' economic. Interestingly, many of the assessments of issues concerned with biodiversity, ecosystem health, poverty, environmental justice and sustainability look at both human and environmental issues, eschewing in the process commitment either to a purely anthropocentric or purely non-anthropocentric ethic (Hayward and O'Neill 1997, and Dobson 1999 for collections of essays looking at the links between sustainability, justice, welfare and the distribution of environmental goods).

Other interdisciplinary approaches link environmental ethics with biology, policy studies, public administration, political theory, cultural history, post-colonial theory, literature, geography, and human ecology (for some examples, see Norton, Hutchins, Stevens, Maple 1995, Shrader-Frechette 1984, Gruen and Jamieson (eds.) 1994, Karliner 1997, Diesendorf and Hamilton 1997). The newest collection on environmental ethics (Schmidtz and Willott 2002) contains, in addition to readings on the questions discussed in the present article, sections devoted explicitly to cost-benefit analysis and environmental policy, the impact of cities on resource consumption, poverty as an environmental problem, sustainability and the growth of human population. This is in keeping with the developing philosophical interest in ethical analysis of policy fundamentals. The future development of environmental ethics may depend on these, and other interdisciplinary synergies, as much as on its anchorage within philosophy.

Communitarianism

Modern-day communitarianism began in the upper reaches of Anglo-American academia in the form of a critical reaction to John Rawls landmark 1971 book *A Theory of Justice*.[1] Drawing primarily upon the insights of Aristotle and Hegel, political philosophers such as Alasdair MacIntyre, Michael Sandel, Charles Taylor and Michael Walzer disputed Rawls assumption that the principal task of government is to secure and distribute fairly the liberties and economic resources individuals need to lead freely chosen lives. These critics of liberal theory never did identify themselves with the communitarian movement (the communitarian label was pinned on them by others, usually critics)[2], much less offer a grand communitarian theory as a systematic alternative to liberalism. Nonetheless, certain core arguments meant to contrast with liberalisms devaluation of community recur in the works of the four theorists named above,[3] and for purposes of clarity one can distinguish between claims of three sorts: methodological claims about the importance of tradition and social context for moral and political reasoning, ontological or metaphysical claims about the social nature of the self, and normative claims about the value of community.[4]

This essay is therefore divided in three parts, and for each part I present the main communitarian claims, followed by an argument (in each part) that philosophical concerns in the 1980s have largely given way to the political concerns that motivated much of the communitarian critique in the first place.

1. Universalism Versus Particularism

Communitarians have sought to deflate the universal pretensions of liberal theory. The main target has been Rawls description of the original position as an ‘Archemedian point’ from which the structure of a social system can be appraised, a position whose special virtue is that it allows us to regard the human

condition 'from the perspective of eternity',[5] from all social and temporal points of view. Whereas Rawls seemed to present his theory of justice as universally true, communitarians argued that the standards of justice must be found in forms of life and traditions of particular societies and hence can vary from context to context. Alasdair MacIntyre and Charles Taylor argued that moral and political judgment will depend on the language of reasons and the interpretive framework within which agents view their world, hence that it makes no sense to begin the political enterprise by abstracting from the interpretive dimensions of human beliefs, practices, and institutions.[6] Michael Walzer developed the additional argument that effective social criticism must derive from and resonate with the habits and traditions of actual people living in specific times and places. Even is there is nothing problematic about a formal procedure of universalizability meant to yield a determinate set of human goods and values, 'any such set would have to be considered in terms so abstract that they would be of little use in thinking about particular distributions.'[7] In short, liberals who ask what is just by abstracting from particular social contexts are doomed to philosophical incoherence and liberal theorists who adopt this method to persuade people to do the just thing are doomed to political irrelevance.

Rawls has since tried to eliminate the universalist presuppositions from his theory. In *Political Liberalism*,[8] he argues in a communitarian vein that his conception of the person as impartial citizen provides the best account of liberal-democratic political culture and that his political aim is only to work out the rules for consensus in political communities where people are willing to try for consensus. In the *Law of Peoples*,[9] he explicitly allows for the possibility that liberalism may not be exportable at all times and places, sketching a vision of a 'decent, well-ordered society' that liberal societies must tolerate in the international realm. Such a society, he argues, need not be democratic, but it must be non-aggressive towards other communities, and internally it must have a 'common good conception of justice', a 'reasonable consultation hierarchy', and it must secure basic human rights. Having said that, one still gets the sense that the liberal vision laid out in *A Theory of Justice* is the best possible political ideal, one that all rational individuals would want if they were able to choose between the available political alternatives. There may be justifiable non-liberal regimes, but these should be regarded as second best to be tolerated and perhaps respected, not idealized or emulated.

Other liberal theorists have taken a harder line against communitarian concessions, arguing that liberal theory can and should present itself as a universally valid ideal. Brian Barry, for one, opens his widely cited book *Justice as Impartiality* by boldly affirming the universality of his theory: 'I continue to believe in the possibility of putting forward a universally valid case in favor of liberal egalitarian principles'.[10] Barry does recognize that a theory of justice must be anchored in substantive moral considerations, but his normative vision appears to be limited to the values and practices of liberal Western societies. He seems distinctly uninterested in learning anything worthwhile from non-Western political traditions for example, his discussion of things Chinese is confined to brief criticisms of the Cultural Revolution and the traditional practice of foot-binding. One might consider the reaction to a Chinese intellectual who puts forward a universal theory of justice that draws on the Chinese political tradition for inspiration and completely ignores the history and moral argumentation in Western societies, except for brief criticisms of slavery and imperialism.

Still, it must be conceded that 1980s communitarian theorists were less-than-successful at putting forward attractive visions of non-liberal societies. The communitarian case for pluralism for the need to respect and perhaps learn from non-liberal societies that may be as good as, if not better than, the liberal societies of the West may have been unintentionally undermined by their own use of (counter) examples. In *After Virtue*, Alasdair MacIntyre defended the Aristotelian ideal of the intimate, reciprocating local community bound by shared ends, where people simply assume and fulfill socially given roles.[11] But this pre-modern Gemeinschaft conception of an all-encompassing community that members unreflectively endorse seemed distinctly ill-suited for complex and conflict-ridden large-scale industrialized societies. In *Spheres of Justice,* Michael Walzer pointed to the Indian caste system, ‘where the social meanings are integrated and hierarchical’[12] as an example of a non-liberal society that may be just according to its own standards. Not surprisingly, few readers were inspired by this example of non-liberal justice (not to mention the fact that many contemporary Indian thinkers view the caste system as an unfortunate legacy of the past that Indians should strive hard to overcome). In short, this use of ill-informed examples may have unintentionally reinforced the view that there are few if any justifiable alternatives to liberalism in modern societies. Communitarians could score some theoretical points by urging liberal thinkers to be cautious about developing universal arguments founded exclusively on the moral argumentation and political experience of Western liberal societies, but few thinkers would really contemplate the possibility of non-liberal practices appropriate for the modern world so long as the alternatives to liberalism consisted of Golden Ages, caste societies, fascism, or actually-existing communism. For the communitarian critique of liberal universalism to have any lasting credibility, thinkers need to provide compelling counter-examples to modern-day liberal-democratic regimes and 1980s communitarians came up short.

By the 1990s, fairly abstract methodological disputes over universalism versus particularism faded from academic prominence, and the debate now centers on the theory and practice of universal human rights. This is largely due to the increased political salience of human rights since the collapse of communism in the former Soviet bloc. On the liberal side, the new, more political voices for liberal universalism have been represented by the likes of Francis Fukuyama, who famously argued that liberal democracys triumph over its rivals signifies the end of history.[13] This view also revived (and provoked) the second wave communitarian critique of liberal universalism and the debate became much more concrete and political in orientation.

Needless to say, the brief moment of liberal euphoria that followed the collapse of the communism in the Soviet bloc has given way to a sober assessment of the difficulties of implementing liberal practices outside the Western world. It is now widely recognized that brutal ethnic warfare, crippling poverty, environmental degradation, and pervasive corruption, to name some of the more obvious troubles afflicting the developing world, pose serious obstacles to the successful establishment and consolidation of liberal democratic political arrangements. But these were seen as unfortunate (hopefully temporary) afflictions that may delay the end of history when liberal democracy has finally triumphed over its rivals. They were not meant to pose a challenge to the *ideal* of liberal democracy. It was widely assumed that liberal democracy is something that all rational individuals *would* want if they could get it.

The deeper challenge to Western liberal democracy has emerged from the East Asian region.[14] In the 1990s, the debate revolved around the notion of Asian values, a term devised by several Asian officials and their supporters for the purpose of challenging Western-style civil and political freedoms. Asians, they claim, place special emphasis upon family and social harmony, with the implication that those in the chaotic and crumbling societies of the West should think twice about intervening in Asia for the sake of promoting human rights and democracy. As Singapores Lee Kuan Yew put it, Asians have ‘little doubt that a society with communitarian values where the interests of society take precedence over that of the individual suits them better than the individualism of America’.[15] Such claims attracted international attention primarily because East Asian leaders seemed to be presiding over what a recent U.N. human development report called ‘the most sustained and widespread development miracle of the twentieth century, perhaps all history’.[16] In 1997-98, however, the East Asian miracle seemed to have collapsed. And it looks like Asian values was one casualty of the crisis.

The political factors that focused attention on the East Asian challenge remain in place, however. East Asian economies (with the notable exception of Indonesia) have been slowly recovering. China in particular looks set to become an economic and political heavyweight with the power to seriously challenge the hegemony of Western liberal democratic values in international fora. Thus, one hears frequent calls for cross-cultural dialogue between the West and the East designed to understand and perhaps learn from the other side. Failing to take seriously East Asian political perspectives risks widening misunderstandings and setting the stage for hostilities that could have been avoided.

From a theoretical point of view, however, it must be conceded that the official debate on Asian values has not provided much of a challenge to dominant Western political outlooks. The main problem is that the debate has been led by Asian leaders who seem to be motivated primarily by political considerations, rather than by a sincere desire to make a constructive contribution to the debate on universalism versus particularism. Thus, it was easy to dismiss rightly so, in most cases the Asian challenge as nothing but a self-serving ploy by government leaders to justify their authoritarian rule in the face of increasing demands for democracy at home and abroad.

Still, it would be a mistake to assume that nothing of theoretical significance has emerged from East Asia. The debate on Asian values has also prompted critical intellectuals in the region to reflect on how they can locate themselves in a debate on human rights and democracy in which they had not previously played a substantial part. Neither wholly rejecting nor wholly endorsing the values and practices ordinarily realized through a liberal democratic political regime, these intellectuals are drawing on their own cultural traditions and exploring areas of commonality and difference with the West. Though often less provocative than the views of their governments in the sense that few argue for the wholesale rejection of Western-style liberal democracy with an East Asian alternative these unofficial East Asian viewpoints may offer more lasting contributions to the debate. Let me (briefly) note three relatively persuasive East Asian arguments for cultural particularism that contrast with traditional Western arguments for liberal universalism:[17]

1. Cultural factors can affect the *prioritizing* of rights, and this matters when rights conflict and it

must be decided which one to sacrifice. In other words, different societies may rank rights differently, and even if they face a similar set of disagreeable circumstances they may come to different conclusions about the right that needs to be curtailed. For example, U.S. citizens may be more willing to sacrifice a social or economic right in cases of conflict with a civil or political right: if neither the constitution nor a majority of democratically elected representatives support universal access to health care, then the right to health care regardless of income can be curtailed. In contrast, the Chinese may be more willing to sacrifice a civil or political liberty in cases of conflict with a social or economic right: there may be wide support for restrictions on the internal movement of farmers if these are necessary to guarantee the right of subsistence. Different priorities assigned to rights can also matter when it must be decided how to spend scarce resources. For example, East Asian societies with a Confucian heritage will place great emphasis upon the value of education, and they may help to explain the large amount of spending on education compared to other societies with similar levels of economic development.

2. Cultural factors can affect the *justification* of rights. In line with the arguments of 1980s communitarians such as Michael Walzer, it is argued that justifications for particular practices valued by Western-style liberal democrats should not be made by relying on the abstract and unhistorical universalism that often disables Western liberal democrats. Rather, they should be made from the inside, from specific examples and argumentative strategies that East Asians themselves use in everyday moral and political debate. For example, the moral language (shared even by some local critics of authoritarianism) tends to appeal to the value of community in East Asia, and this is relevant for social critics concerned with practical effect. One such communitarian argument is that democratic rights in Singapore can be justified on the grounds that they contribute to strengthening ties to such communities as the family and the nation (see below, section III).
3. Cultural factors can provide moral foundations for *distinctive* political practices and institutions (or at least different from those found in Western-style liberal democracies). In East Asian societies influenced by Confucianism, for example, it is widely held that children have a profound duty to care for elderly parents, a duty to be forsaken only in the most exceptional circumstances.[18] In political practice, it means that East Asian governments have an obligation to provide the social and economic conditions that facilitate the realization of this duty. Political debate tends to center on the question of whether the right to filial piety is best realized by means of a law that makes it mandatory for children to provide financial support for elderly parents as in mainland China, Japan, and Singapore or whether the state should rely more on indirect methods such as tax breaks and housing benefits that simply make at-home care for the elderly easier, as in Korea and Hong Kong. But the argument that there is a pressing need to secure this duty in East Asia is not a matter of political controversy.

Thinkers influenced by East Asian cultural traditions such Confucianism have also argued for distinctive as-yet-unrealized political practices and institutions that draw on widely-held cultural values for inspiration. For example, the Korean scholar Hahm Chaihark argues for the need to revive and adapt for the contemporary era the Confucian censorate, a traditional institution that played the role of monitoring the dealings of the Emperor.[19]

In contrast to 1980s communitarian thinkers, East Asian critics of liberal universalism have succeeded in pointing to particular non-liberal practices and institutions that may be appropriate for the contemporary world. Some of these may be appropriate only for societies with a Confucian heritage, others may also offer insights for mitigating the excesses of liberal modernity in the West. What cannot be denied is that they have carried forward the debate beyond the implausible alternatives to liberalism offered by 1980s communitarian thinkers.

It is worth emphasizing, however, that contemporary communitarians have not been merely defending parochial attachments to particular non-liberal moralities. Far from arguing that the universalist discourse on human rights should be entirely displaced with particular, tradition-sensitive political language, they have criticized liberals for not taking universality seriously enough, for failing to do what must be done to make human rights a truly universal ideal. These communitarians -- let us label them the cosmopolitan critics of liberal universalism -- have suggested various means of improving the philosophical coherence and political appeal of human rights.

In fact, there is little debate over the desirability of a core set of human rights, such as prohibitions against slavery, genocide, murder, torture, prolonged arbitrary detention, and systematic racial discrimination. These rights have become part of international customary law, and they are not contested in the public rhetoric of the international arena. Of course many gross violations occur off the record, and human rights groups such as Amnesty International have the task of exposing the gap between public allegiance to rights and the sad reality of ongoing abuse. This is largely practical work, however. There is not much point writing about or deliberating about the desirability of practices that everyone condemns at the level of principle.

But political thinkers and activists around the world can and do take different sides on many pressing human rights concerns that fall outside what Walzer terms the ‘minimal and universal moral code’.[20] This gray area of debate includes criminal law, family law, womens rights, social and economic rights, the rights of indigenous peoples, and the attempt to universalize Western-style democratic practices. The question is: how can the current thin list of universal human rights be expanded to include some of these contested rights?

Charles Taylor has put forward the following proposal.[21] He imagines a cross-cultural dialogue between representatives of different traditions. Rather than argue for the universal validity of their views, however, he suggests that participants should allow for the possibility that their own beliefs may be mistaken. This way, participants can learn from each others ‘moral universe’. There will come a point, however, when differences cannot be reconciled. Taylor explicitly recognizes that different groups, countries, religious communities, and civilizations hold incompatible fundamental views on theology, metaphysics, and human nature. In response, Taylor argues that a ‘genuine, unforced consensus’ on human rights norms is possible only if we allow for disagreement on the ultimate justifications of those norms. Instead of defending contested foundational values when we encounter points of resistance (and thus condemning the values we do not like in other societies), we should try to abstract from those beliefs for the purpose of working out an ‘overlapping consensus’ of human rights norms. As Taylor puts it, ‘we

would agree on the norms while disagreeing on why they were the right norms, and we would be content to live in this consensus, undisturbed by the differences of profound underlying belief'.[22]

While Taylors proposal moves the debate on universal human rights forward, it still faces certain difficulties. For one thing, it may not be realistic to expect that people will be willing to abstract from the values they care deeply about during the course of a global dialogue on human rights. Even if people agree to abstract from culturally specific ways of justifying and implementing norms, the likely outcome is a withdrawal to a highly general, abstract realm of agreement that fails to resolve actual disputes over contested rights. For example, participants in a cross-cultural dialogue can agree on the right not to be subject to cruel and unusual punishment while radically disagreeing upon what this means in practice a committed Muslim can argue that theft can justifiably be punished by amputation of the right hand,[23] whereas a Western liberal will want to label this an example of cruel and unusual punishment.

As we have seen, the debate on universalism versus particularism has moved from fairly abstract methodological disputes between Anglo-American philosophers to relatively concrete international political disputes between philosophers, social scientists, government officials, and NGO activists. The distinctive communitarian contribution has been to cast doubt on universal theories grounded exclusively in the liberal moralities of the Western world, on the grounds that cultural particularity should both make one sensitive to the possibility of justifiable areas of difference between the West and the rest and to the need for more cross-cultural dialogue for the purpose of improving the current thin human rights regime. Various contributions from East Asia and elsewhere have given some meat to these challenges to liberal universalism. In any case, let us now turn to the second main area of controversy between liberals and communitarians -- the debate over the self that has similarly moved from philosophy to politics.

2. The Debate Over the Self

Communitarian thinkers in the 1980s such as Michael Sandel and Charles Taylor argued that Rawlsian liberalism rests on an overly individualistic conception of the self. Whereas Rawls argues that we have a supreme interest in shaping, pursuing, and revising our own life-plans, he neglects the fact that our selves tend to be defined or constituted by various communal attachments (eg, ties to the family or to a religious tradition) so close to us that they can only be set aside at great cost, if at all. This insight led to the view that politics should not be concerned solely with securing the conditions for individuals to exercise their powers of autonomous choice, as we also need to sustain and promote the social attachments crucial to our sense of well-being and respect, many of which have been involuntarily picked up during the course of our upbringing. First, however, let us review the ontological or metaphysical debate over the self that led to this political conclusion.

In an influential essay titled 'Atomism', Charles Taylor objected to the liberal view that 'men are self-sufficient outside of society'.[24] Instead, Taylor defends the Aristotelian view that 'Man is a social animal, indeed a political animal, because he is not self-sufficient alone, and in an important sense is not self-sufficient outside a polis'.[25] Moreover, this atomistic view of the self can undermine liberal

society, because it fails to grasp the extent to which liberalism presumes a context where individuals are members of, and committed to, a society that promotes particular values such as freedom and individual diversity. Fortunately, most people in liberal societies do not really view themselves as atomistic selves.

But do liberal thinkers actually defend the idea that the self is created *ex-nihilo*, outside of any social context and that humans can exist (and flourish) independently of all social contexts? In fact, Taylors essay was directed at the libertarian thinker Robert Nozick. As it turns out, the communitarian critique of the atomistic self does not apply to Rawslian liberalism: in Part III of *Theory of Justice*, Rawls pays close attention to the psychological and social conditions that facilitate the formation of liberal selves committed to justice. But few readers ever got to Part III of Rawls massive tome, so communitarians got quite a bit of mileage from their critique of liberal atomism. This charge didnt stick, however.

While liberals may not have been arguing that individuals can *completely* extricate themselves from their social context, the liberal valuation of choice still seemed to suggest an image of a subject who impinges his will on the world.[26] Drawing on the insights of Heidegger and Wittgenstein, communitarians argued that this view neglects the extent to which individuals are embodied agents in the world. Far from acting in ways designed to realize an autonomously arrived-at life-plan, vast areas of our lives are in fact governed by unchosen routines and habits that lie in the background. More often than not we act in ways specified by our social background when we walk, dress, play games, speak, and so on without having formulated any goals or made any choices. It is only when things break down from the normal, everyday, unchosen mode of existence that we think of ourselves as subjects dealing with an external world, having the experience of formulating various ways of executing our goals, choosing from among those ways, and accepting responsibility for the outcomes of our actions. In other words, traditional intentionality is introduced at the point that our ordinary way of coping with things is insufficient. Yet this breakdown mode is what we tend to notice, and philosophers have therefore argued that most of our actions are occasioned by processes of reflection. Liberals have picked up this mistaken assumption, positing the idea of a subject who seeks to realize an autonomously arrived-at life-plan, losing sight of the fact that critical reflection upon ones ends is nothing more than one possibility that arises when our ordinary ways of coping with things is insufficient to get things done.

Some liberals have replied by recognizing the point that vast areas of our lives are governed by unchosen habits and routines, that the deliberate, effortful, choosing subject mode may be the exception rather than the rule. They emphasize, however, that the main justification for a liberal politics concerned primarily with securing the conditions for individuals to lead autonomous lives rests on the possibility and desirability of *normative* self-determination, that is,on the importance of making choices with respect to things that we *value*.[27] While it may be true that certain communal practices often, or even mostly, guide our behavior behind our backs, it doesnt follow that those practices ought to be valued, or reflectively endorsed in non-ordinary moments of existence, much less that the government ought somehow to promote these practices. And what liberals care about ultimately is the provision of the rights, powers, and opportunities that individuals need to develop and implement their own conceptions of the good life.

This qualified version of the liberal self, however, still seems to imply is that moral outlooks are, or should be, the product of individual choice. Ones social world, communitarians can reply, provides more than non-moral social practices like table manners and pronunciation norms it also provides some sort of orientation in *moral* space. We cannot make sense of our moral experience unless we situate ourselves within this given moral space, within the authoritative moral horizons. What Charles Taylor calls ‘higher, strongly evaluated goods’[28] -- the goods we should feel committed to, those that generate moral obligations on us regardless of our actual preferences are not somehow invented by individuals, but rather they are located within the social world which provides ones framework of the lower and the higher. Thus, the liberal ideal of a self who freely invents her own moral outlook, or private conception of the good, cannot do justice to our actual moral experience.

But once again, liberals need not deny the assumption that our social world provides a framework of the higher and the lower nor need it be presumed that we must regard our own moral outlook as freely invented. Will Kymlicka, for example, explicitly recognizes that things have worth for us in so far as they are granted significance by our culture, in so far as they fit into a pattern of activities which is recognized by those sharing a certain form of life as a way of leading a good life.[29] That ones social world provides the range of things worth doing, achieving, or being does not, however, undermine the liberal emphasis on autonomy, for there is still substantial room for individual choice to be made within this set. The best life is still the one where the individual *chooses* what is worth doing, achieving, or being, though it may be that this choice has to be made within certain framework which is itself unchosen.

Communitarians can reply by casting doubt on the view that choice is *intrinsically* valuable, that a certain moral principle or communal attachment is more valuable simply because it has been chosen following deliberation among alternatives by an individual subject. If we have a highest-order interest in choosing our central projects and life-plans, regardless of what is chosen, it ought to follow that there is something fundamentally wrong with unchosen attachments and projects. But this view violates our actual self-understandings. We ordinarily think of ourselves, Michael Sandel says, ‘as members of this family or community or nation or people, as bearers of this history, as sons or daughters of that revolution, as citizens of this republic’,[30] social attachments that more often than not are involuntarily picked up during the course of our upbringing, rational choice having played no role whatsoever. I didnt choose to love my mother and father, to care about the neighborhood in which I grew up, to have special feelings for the people of my country, and it is difficult to understand why anyone would think I have chosen these attachments, or that I ought to have done so. In fact, there may even be something distasteful about someone who questions the things he or she deeply cares about certainly no marriage could survive too long if fundamental understandings regarding love and trust were constantly thrown open for discussion! Nor is it obvious that, say, someone who performs a good deed following prolonged calculation of pros and cons is morally superior than a Mother-Teresa type who unreflectively, spontaneously acts on behalf of other peoples interests.

Liberals can reply that the real issue is not the desirability of choice, but rather the *possibility* of choice. There may well be some unchosen attachments that need not be critically reflected upon and endorsed,

and it may even be the case that excessive deliberation about the things we care about can occasionally be counter-productive. But some of our ends may be problematic and that is why we have a fundamental interest in being able to question and revise them. Most important is not choosing our own life-plans; rather, liberalism founded on the value of self-determination requires only that we be able to critically evaluate our ends *if need be*, hence that 'no end or goal is exempt from possible re-examination'.[31] For example, an oppressed woman has a fundamental interest in being able to critically reflect upon traditional understandings of what it means to be a good wife and mother, and it would be unjust to foreclose her freedom to radically revise her plans.

This response, however, still leaves open the possibility of a deep challenge to liberal foundations. Even we are indeed able to reexamine some attachments, the problem for liberalism arises if there are others so fundamental to our identity that they cannot be set aside, and that any attempt to do so will result in serious and perhaps irreparable psychological damage. In fact, this challenge to liberalism would only require that communitarians be able to identify one end one communal attachment, for example so constitutive to ones identity that it cannot be revised and rejected. A psychoanalyst, for example, may want to argue that (at least in some cases) it is impossible to choose to shed the attachment one feels for ones mother, and that an attempt may lead to perverse and unintended consequences. A feminist theorist may point to the mother-child relationship as an example of a constitutive feature of ones identity and argue that any attempt to deny this fails to be sensitive to womens special needs and experiences.[32] An anthropologist may argue on the basis of field observations that it is impossible for an Inuit person from Canadas far north to suddenly decide to stop being an Inuit and that the only sensible response is to recognize and accept this constitutive feature of his identity. Or a gay liberation activist may claim that it is both impossible and undesirable for gays to repress their biologically-given sexual identity. These arguments are not implausible, and they seem to challenge the liberal view that no particular end or commitment should be beyond critical reflection and open to revision.

Let us assume, for the sake of argument, that we can identify one particular attachment so deeply-embedded that it is impossible to really bring to conscious awareness and so significant for ones well-being that an individual can only forsake commitment to its good at the cost of being seriously psychologically disturbed. This end is beyond willed change and one loses a commitment to it at the price of being thrown into a state of disorientation where one is unable to take a stand on many things of significance.[33] Does this really threaten liberal politics? It may, if liberal politics really rests on the liberal self. Fortunately, that is not the case. Rereading some of the communitarian texts from the 1980s, there seems to have been an assumption that once you expose faulty foundations regarding the liberal self, the whole liberal edifice will come tumbling down. The task is to criticize the underlying philosophy of the self, win people on your side, and then we can move on to a brand new communitarian society that owes nothing to the liberal tradition. This must have been an exhilarating time for would-be revolutionaries, but more level-headed communitarians soon realized that overthrowing liberal rights was never part of the agenda. Even if liberals are wrong to deny the existence of constitutive ends even if the philosophical justifications for a liberal form of social organization founded on the value of reflective choice are rotten to the core -- there are still many, relatively pragmatic reasons for caring about rights in the modern world. To name some of the more obvious benefits, liberal rights contribute to security, political stability and economic modernization.

In short, the whole debate about the self appears to have been somewhat misconceived. Liberals were wrong to think they needed to provide iron-clad philosophies of the self to justify liberal politics, and communitarians were wrong to think that challenging those foundations was sufficient to undermine liberal politics. Not surprisingly, both sides soon got tired of debating the pros and cons of the liberal self. By the early 1990s, this liberal-communitarian debate over the self had effectively faded from view in Anglo-American philosophy.[34]

So what remains of the communitarian conception of the self? What may be distinctive about communitarians is that they are more inclined to argue that individuals have a vital interest in leading decent communal lives, with the political implication that there may be a need to sustain and promote the communal attachments crucial to our sense of well-being. This is not necessarily meant to challenge the liberal view that some of our communal attachments can be problematic and may need to be changed, thus that the state needs to protect our powers to shape, pursue, and revise our own life-plans. But our interest in community may occasionally conflict with our other vital interest in leading freely chosen lives, and the communitarian view is that the latter does not automatically trump the former in cases of conflict. On the continuum between freedom and community, communitarians are more inclined to draw the line towards the latter.

But these conflicts cannot be resolved in the abstract. Much turns on empirical analyses of actual politics to what extent our interest in community is indeed threatened by excess liberal politics, to what extent the state can play a role in remedying the situation, to what extent the nourishment of communal ties should be left to civil society, and so on. This is where the political communitarians of the last decade have shed some light. Let us now turn to the politics of community, the third major strand of the communitarian thought.

3. The Politics of Community

In retrospect, it seems obvious that communitarian critics of liberalism may have been motivated not so much by philosophical concerns as by certain pressing political concerns, namely, the negative social and psychological effects related to the atomistic tendencies of modern liberal societies. Whatever the soundness of liberal principles, in other words, the fact remains that many communitarians seems worried by a perception that traditional liberal institutions and practices have contributed to, or at least do not seem up to the task of dealing with, such modern phenomena as alienation from the political process, unbridled greed, loneliness, urban crime, and high divorce rates. And given the seriousness of these problems in the United States, it was perhaps inevitable that a second wave of 1990s communitarians such as Amitai Etzioni and William Galston would turn to the more practical political terrain of emphasizing social responsibility and promoting policies meant to stem the erosion of communal life in an increasingly fragmented world.[35] Much of this thinking has been carried out in the flagship communitarian periodical, *The Responsive Community*, which is edited by Amitai Etzioni and includes contributions by an eclectic group of philosophers, social scientists, and public policy makers. Etzioni is also the director of a think-tank, *Institute for Communitarian Policy Studies*, that produces working

papers and advises government officials in Washington.[36]

Such political communitarians blame both the left and the right for our current malaise.[37] The political left is chastised not just for supporting welfare rights economically unsustainable in an era of slow growth and aging populations, but also for shifting power away from local communities and democratic institutions and towards centralized bureaucratic structures better equipped to administer the fair and equal distribution of benefits, thus leading to a growing sense of powerlessness and alienation from the political process. Moreover, the modern welfare state with its universalizing logic of rights and entitlements has undermined family and social ties in civil society by rendering superfluous obligations to communities, by actively discouraging private efforts to help others (eg, union rules and strict regulations in Sweden prevent parents from participating voluntarily in the governance of day care centers to which they send their children), and even by providing incentives that discourage the formation of families (eg, welfare payments are cut off in most American states if a recipient marries a working person) and encourage the break-up of families (eg, no-fault divorce in the US is often financially rewarding for the non custodial parent, usually the father).

Libertarian solutions favored by the political right have contributed even more directly to the erosion of social responsibilities and valued forms of communal life, particularly in the UK and the US. Far from producing beneficial communal consequences, the invisible hand of unregulated free-market capitalism undermines the family (eg, few corporations provide enough leave to parents of newborn children), disrupts local communities (eg, following plant closings or the shifting of corporate headquarters), and corrupts the political process (eg, since the mid-seventies special economic interests in the US have gained more power by drawing on political action committees to fund political representatives, with the consequence that representatives dependent on PAC money for their political survival no longer represent the community at large). Moreover, the valorization of greed in the Thatcher/Reagan era justified the extension of instrumental considerations governing relationships in the marketplace into spheres previously informed by a sense of uncalculated reciprocity and civil obligation. This trend has been reinforced by increasing globalization, which pressures states into conforming to the dictates of the international marketplace.

More specifically in the American context, communitarian thinkers such as Mary Ann Glendon indict a new version of rights discourse that has achieved dominance of late.[38] Whereas the assertion of rights was once confined to matters of essential human interest, a strident rights rhetoric has colonized contemporary political discourse, thus leaving little room for reasoned discussion and compromise, justifying the neglect of social responsibilities without which a society could not function, and ultimately weakening all appeals to rights by devaluing the really important ones.

To remedy this imbalance between rights and responsibilities in the US, political communitarians propose a moratorium on the manufacture of new rights and changes to our habits of the heart away from exclusive focus on personal fulfillment and towards concern with bolstering families, schools, neighborhoods, and national political life, changes to be supported by certain public policies. Notice that this proposal takes for granted basic civil and political liberties already in place, thus alleviating the

concern that communitarians are embarking on a slippery slope to authoritarianism. Still, there may be a concern that marginalized groups demanding new rights, eg, homosexual couples seeking the right to legally sanctioned marriage, will be paying the price for the excesses of others if the communitarian proposal to declare a moratorium on the minting of new rights is put into effect.

More serious from the standpoint of those generally sympathetic to communitarian aspirations, however, is the question of what exactly this has to do with community. For one thing, Etzioni himself seeks to justify his policies with reference to need to maintain a balance between social *order* and freedom,[39] as opposed to appealing to the importance of community. But there is nothing distinctively communitarian about the preoccupation with social order; both liberals such as John Stuart Mill and Confucian conservatives affirm the need for order. And when the term community is employed by political communitarians, it seems to mean anything they want it to mean. Worse, as Elizabeth Frazer has argued, it has often been used to justify hierarchical arrangements and delegitimize areas of conflict and contestation in modern societies.[40]

Still, it is possible to make sense of the term community as a normative ideal.[41] Communitarians begin by positing a need to experience our lives as bound up with the good of the communities out of which our identity has been constituted. This excludes contingent attachments such as golf-club memberships, that do not usually bear on ones sense of identity and well-being (the co-authors of *Habits of the Heart*[42] employ the term ‘lifestyle enclaves’ to describe these attachments). Unlike pre-modern defenders of *Gemeinshaft*, however, it is assumed that there are *many* valued forms of communal life in the modern world. So the distinctive communitarian political project is to identify valued forms of community and to devise policies designed to protect and promote them, without sacrificing too much freedom. Typically, communitarians would invoke the following types of communities:

1. Communities of place, or communities based on geographical location. This is perhaps the most common meaning associated with the word community. In this sense, community is linked to locality, in the physical, geographical sense of a community that is located somewhere. It can refer to a small village or a big city. A community of place also has an affective component it refers to the place one calls home, often the place where one is born and bred and the place where one would like to end ones days even if home is left as an adult. At the very least, communitarians posit an interest in identifying with familiar surroundings.

   In terms of political implications, it means that, for example, political authorities ought to consider the existent character of the local community when considering plans for development (Jane Jacobs famously documented the negative effects of razing, instead of renovating, run-down tenements that are replaced by functionally adequate but characterless low-income housing blocs[43]). Other suggestions to protect communities of place include: granting community councils veto power over building projects that fail to respect existent architectural styles; implementing laws regulating plant closures so as to protect local communities from the effects of rapid capital mobility and sudden industrial change; promoting local-ownership of corporations;[44] and imposing restrictions on large-scale discount outlets such as Wal-Mart that

threaten to displace small, fragmented, and diverse family and locally owned stores.[45]

2. Communities of memory, or groups of strangers who share a morally-significant history. This term first employed by the co-authors of *Habits of the Heart* refers to imagined communities that have a shared history going back several generations. Besides tying us to the past, such communities turn us towards the future members strive to realize the ideals and aspirations embedded in past experiences of those communities, seeing their efforts as being, in part, contributions to a common good. They provide a source of meaning and hope in peoples lives. Typical examples include the nation and language-based ethnocultural groups.

   In Western liberal democracies, this typically translates into various nation-building exercises meant to nourish the bonds of commonality that tie people to their nations, such as national service and national history lessons in school textbooks. Self-described republicans such as Michael Sandel place special emphasis upon the national political community and argue for measures that increase civic engagement and public-spiritedness.[46] However, there is increased recognition of the multi-national nature of contemporary states, and modern Western states must also try to make room for the political rights of minority groups. These political measures have been widely discussed in the recent literature on nationalism, citizenship, and multiculturalism.[47]
3. Psychological communities, or communities of face-to-face personal interaction governed by sentiments of trust, co-operation, and altruism. This refers to a group of persons who participate in common activity and experience a psychological sense of togetherness as shared ends are sought. Such communities, based on face-to-face interaction, are governed by sentiments of trust, cooperation, and altruism in the sense that constituent members have the good of the community in mind and act on behalf of the communitys interest. They differ from communities of place by not being necessarily defined by locality and proximity. The differ from communities of memory in the sense that they are more real, they are typically based on face to face social interaction at one point in time and consequently tend to be restricted in size.[48] The family is the prototypical example. Other examples include small-scale work or school settings founded on trust and social cooperation.

   Communitarians tend to favor policies designed to protect and promote ties to the family and family-like groups. This would include such measures as encouraging marriage and increasing the difficulty of legal marriage dissolution. These policies are supported by empirical evidence that points to the psychological and social benefits of marriage.[49] Communitarians also favor political legislation that can help to restructure education in such a way that peoples deepest needs in membership and participation in psychological communities are tapped at a young age. The primary school system in Japan, where students learn about group cooperation and benefits and rewards are assigned to the classroom as a whole rather than to individual students, could be a useful model.[50]

What makes the political project of communitarianism distinctive is that it involves the promotion all three forms of valued communal life. This leads, however, to the worry that seeking the goods of various communities may conflict in practice. Etzioni, for example, argues for a whole host of pro-family

measures: mothers and fathers should devote more time and energy to parenting (in view of the fact that most childcare centers do a poor job of caring for children), labor unions and employers ought to make it easier for parents to work at home, and the government should force corporations to provide six months of paid leave and another year of unpaid leave.[51] The combined effect of these changes of the heart and public policies in all likelihood would be to make citizens into largely private, family-centered persons.

Yet Etzioni also argues that the American political system is corrupt to the core, concluding that only extensive involvement in public affairs by virtuous citizens can remedy the situation: ‘once citizens are informed, they must make it their civic duty to *organize others* locally, regionally, and nationally to act on their understanding of what it takes to clean up public life in America.’[52] But few can afford sufficient time and energy to devote themselves fully to both family life and public affairs, and favoring one ideal is most likely to erode the other. Surely it is no coincidence that republican America in Jeffersons day relied on active, public-spirited male citizens largely freed from family responsibilities. Conversely, societies composed of persons leading rich and fulfilling family lives (such as contemporary Singapore) tend to be ruled by paternalistic despots who can rely on a compliant, politically apathetic populace.

Communitarians who advocate both increased commitment to public affairs and strengthened ties to the workplace (to the point that it becomes a psychological community) also face the problem of conflicting commitments. Michael Sandel, for example, speaks favorable of ‘proud craftsmen’ in the Jacksonian ear and of Louis Brandeiss idea of ‘industrial democracy, in which workers participated in management and shared responsibilities for running the business.’[53] Identification with the workplace and industrial democracy are said to improve workers civic capacities, but that may not be the case. In the same way that extensive involvement in family life can conflict with commitments to public life, few persons will have sufficient time and energy for extensive participation in both workplace and public affairs. Recall that the republican society of ancient Athens relied on active, public-spirited males freed from the need to work (slaves did most of the drudge labor).

It is also worth noting that devotion to the workplace can undermine family life. As Professor Tatsuo Inoue of Tokyo University argues, Japanese-style communitarianism strong communal identity based on the workplace, with extensive worker participation in management sometimes leads to *karoshi* (death from overwork) and frequently deprives workers of ‘the right to sit down at the dinner table with their families’.[54] Just as liberals (pace Ronald Dworkin) sometimes have to choose between ideals (eg, freedom and equality) that come into conflict with one another if a serious effort is made to realize any one of them fully, so communitarians may have to make some hard choices between valued forms of communal life.

Still, there may be some actual or potential win-win scenarios cases where promoting a particular form of communal life can promote, rather than undermine, other forms -- and political communitarians will of course favor change of this sort. For example, critics have objected to residential community associations, or walled communities, on the grounds that they undermine attachment to the polity at large and erode the social cohesion and trust needed to promote social justice and sustain the democratic

process.[55] Might it then be possible to reform urban planning so that people can nurture strong local communities without undermining attachment to the national community, perhaps even strengthening broader forms of public-spiritedness? Many practical suggestions along these lines have been raised. Architects and urban planners in the US known as the New Urbanists, for example, have proposed various measures to strengthen community building affordable housing, public transport, pedestrian focused environments, and public space as an integral part of neighborhoods that would not have the privatizing consequences of gated communities. The problem, as Gerald Frug points out, is that ‘virtually everything they want to do is now illegal. To promote the new urbanist version of urban design, cities would have revise municipal zoning laws and development policy from top to bottom.’[56] This points to the need for public policy recommendations explicitly designed to favor complementing forms of communal attachments.

Just as it would be wrong to assume that communitarian goals always conflict, so one should allow for the possibility that individual rights and communitarian goals can co-exist and complement each other.[57] In Singapore, for example, it can be argued that more secure democratic rights would have the effect of strengthening commitment to the common national good.[58] The Singapore government does not hide the fact that it makes life difficult for many who aim to enter the political arena on the side of opposition parties: Between 1971 and 1993, according to Attorney General Chan Sek Keong, eleven opposition politicians have been made bankrupt (and hence ineligible to run in elections).[59] Whether intended or not, such actions send an unpatriotic message to the community at large: Politics is a dangerous game for those who havent been specially anointed by the top leadership of the ruling party, so you should stick to your own private affairs. As Singaporean journalist Cherian George puts it, one can hardly blame people for ignoring their social and political obligations ‘when they hear so many cautionary tales: Of Singaporeans whose careers came to a premature end after they voiced dissent; of critics who found themselves under investigation; of individuals who were detained without trial even though they seemed not to pose any real threat; of tapped phones and opened letters’. The moral of these stories: In Singapore, better to mind your own business, make money, and leave politics to the politicians.’[60] Put positively, if the aim is to secure attachment to the community at large, then implementing genuinely competitive elections, including the freedom to run for the opposition without fear of retaliation,[61] is an essential first step.

The Singapore case, however, points to another dimension of the politics of community that brings us back to the communitarian defense of cultural particularism. Democratic reformers in Singapore typically think of democracy in terms of free and fair competitive elections what Western analysts often label minimal democracy. In Hong Kong, the situation is similar the aspiration to full democracy put forward by social critics turns out to mean (nothing more than) an elected legislature and Chief Executive. Put differently, it is quite striking that the republican tradition in communitarian thought with its vision of strong democracy supported by active, public-spirited citizens who participate in political decision-making and held shape the future direction of their society though political debate seems completely absent from political discourse in Singapore and Hong Kong, and perhaps East Asia more generally. Many East Asians are clamoring for secure democratic rights, but this doesnt translate into the demand that all citizens should be committed to politics on an ongoing basis or the view that, as David

Miller puts it, 'politics is indeed a necessary part of the good life'[62]. At one level, this can be explained by the fact that there are no equivalents of Aristotle and Jean-Jacques Rousseau in East Asian philosophy. It can also be argued that republican ideas fail to resonate because East Asians typically place more emphasis on other forms of communal life the family in particular has been important theme in Confucian ethical theory and practice (relative to Western philosophy). To the extent that different forms of communal life do conflict in practice, in short, it may the case that different cultures will draw the line in different places and they may be justified in doing so, if this conforms to the views shared by both defenders and critics of the political *status quo*.

Notes to Communitarianism

Notes

1. See the Bibliographic entry for Rawls 1971.

2. Both Taylor and Walzer identify themselves as liberals in Gutmann 1992. MacIntyre (1991) says 'In spite of rumors to the contrary, I am not and never have been a communitarian'. Sandel (1998) uses the label republican rather than communitarian.

3. For relevant references, see the bibliographies in Avineri and de-Shalit 1992, Bell 1993, Berten *et al*. 1997, Mulhall & Swift 1996, and Rasmussen 1990.

4. This essay draws on the threefold distinction in Bell 1993. For a similar threefold distinction, see Caney 1992. But for an expanded fivefold classification of arguments, see Mulhall & Swift 1996.

5. This is the language Rawls employs on the last page of the first edition of Rawls 1971.

6. See, e.g., Taylor 1985, ch.1; MacIntyre 1978, chs.18-22 and 1988, ch.1. See also the discussion in Benhabib 1992, pp.23-38, 89n4.

13. Fukuama 1992.

14. This section draws on the introduction to Bell 2000. Another challenge to Western-style liberal-

democracy has of course been mounted by Islamic civilization, though Islamic countries have not been as economically and politically successful (compared to East Asia) and therefore fail to pose as significant a challenge the claims of Western liberal-democrats that only capitalism and liberal democracy can cope with the requirements of modernity.

15. Quoted in the *International Herald Tribune*, 9-10 November 1991.

16. Quoted in Barbara Crossette, 'U.N. Survey Finds Rich-Poor Gap Widening', *New York Times*, 15 July 1996.

17. See Bell 2000, ch.1.

18. Interestingly, this moral outlook still seems to inform the practices of Asian immigrants to other societies. According to the *New York Times* (11 August 2001), fewer than one in five whites in the US help care or provide financial support for their parents, in-laws or other relatives, compared with 28% of African-Americans, 34% of Hispanic-Americans and 42% of Asian-Americans. Those who provide the most care also feel the most guilt that they are not doing enough. Almost three-quarters of Asian-Americans say they should do more for their parents, compared with two-thirds of Hispanics, slightly more than half the African-Americans and fewer than half the whites.

25. Taylor 1985, p.190.

26. This section draws on Acts I and III of Bell 1993.

27. See, e.g., Doppelt 1989.

28. See, e.g., Taylor 1989, esp. part I.

29. Kymlicka 1989, p.166.

30. Sandel 1981, p.179.

31. Will Kymlicka 1989, p. 52. See also Dworkin 1989, p. 489, and Macedo 1990, p. 247.

32. See, e.g., Frazer & Lacey 1993, pp.53-60.

33. See Taylor 1989, pp. 26-7.

34. The liberal-communitarian debate over the self has been prominent in non-anglophone publications, however, see e.g., Qiang 1998, chs.5-6. It is also interesting to note that adherents of Confucianism have recently advanced arguments against liberal foundations similar to the claims of 1980s communitarians, also with the apparent aim of undermining the foundations of liberal rights. Joseph Chan (1999) reviews these arguments and finds them wanting, with the proviso that Confucianisms understanding of the scope and justification of rights would differ from Western, rights-based perspectives.

35. For book-length treatments of communitarian politics in the US, see, Etzioni 1993, 1996, and 2001. For a book that derives largely from the UK context see Tams 1998. See also Etzioni's edited books, 1995a, 1995b, and 1998.

36. Both Democrats and Republicans seem to be receptive to communitarian political ideas. The political theorist William Galston, a co-editor of *The Responsive Community* and author of *Liberal Purposes* (Cambridge: Cambridge University Press, 1991), was President Clinton's Domestic Policy Adviser. President Bush has recently unveiled a four-year Communities of Character project that was developed following consultations with Etzioni (*Washington Post*, 29 July 2001). See also Dana Milbank, ‘Is Bush a Communitarian?’, *The Responsive Community* (Spring 2001), pp.4-7.

37. This section draws on Bell 1997.

38. Glendon 1991.

39. See especially Etzioni 1996.

40. Frazer 1999.

41. This section draws on Acts III to V Bell 1993. See also Mason 2000. Mason usefully distinguishes between different levels and kinds of communities, though one can question his argument that the ideal

of global *community* is coherent in principle and useful in practice (in my view, communities are particularistic in nature and presume an inside/outside distinction, and even if this ideal is coherent it is unclear to what extent the ideal of community does much work for defenders of universal liberal principles and global institutions).

45. See Ehrenhalt 1999.

46. Sandel 1996.

47. See, e.g., Kymlicka 1995, Macedo 2000, and Tamir 1993.

48. Though conceptions of the family can also include an imagined component for example, the widespread practice of ancestor worship in East Asian societies with a Confucian heritage suggests that (deceased) ancestors are considered as ongoing participants in the good of the family.

49. See Waite 1996.

50. See Reid 1999, esp. ch.5.

51. See Etzioni 1993, ch.2 and Etzioni 1996, ch.6.

52. Etzioni 1993, p.244.

53. Sandel 1996, pp.170, 213. See also Bell 1997b.

54. Inoue 1993.

55. See McKenzie 1994, and Bell 1995. For a contrasting account, see Rosenblum 1998, ch.4.

56. Frug 1999, pp.152-53. For an account of an actual example of diverse, mixed-income and mixed race urban housing project that contrasts with homogenous, upper-class walled communities, see D'Antonio 1994.

57. See Bell 1995b, for a critique of Etzioni's apparent assumption that rights and particularistic communal commitments always conflict.

58. This argument is developed at length in Bell 2000, ch.4. In the same vein, see Beng-Huat 1995, esp. ch.9.

59. In the latest case (mid-2001), J.B. Jeyaratnam has been declared bankrupt and has had to forfeit his Parliamentary seat.

60. *Straits Times* (Singapore), 11 July 1993.

61. The Singapore state, it must be said, resorts to endlessly creative tactics to curb opposition attempts to reach out to the electorate and communicate alternative ideas and policies. The opposition Singapore Democratic Party was recently informed by the Singapore police that it needed to engage 13 officers for crowd control purposes for a planned national day rally on 26 August 2001, amounting to several thousand dollars. One wonders if the ruling Peoples Action Party needs to pay for its own security for its rallies (not to mention the question of who pays for the undercover officers at opposition rallies).

Nationalism

The term ‘nationalism’ is generally used to describe two phenomena: (1) the attitude that the members of a nation have when they care about their national identity, and (2) the actions that the members of a nation take when seeking to achieve (or sustain) some form of political sovereignty. (1) raises questions about the concept of nation (or national identity), which is often defined in terms of common origin, ethnicity, or cultural ties, and while an individual's membership in a nation is often regarded as involuntary, it is sometimes regarded as voluntary. (2) raises questions about the whether sovereignty must be understood as the acquisition of full statehood with complete authority for domestic and international affairs, or whether something less is required.

It is traditional, therefore, to distinguish nations from states -- whereas a nation often consists of an ethnic or cultural community, a state is a political entity with a high degree of sovereignty. While many states are nations in some sense, there are many nations which are not fully sovereign states. As an example, the Native American Iroquois constitute a nation but not a state, since they do not possess the requisite political authority over their internal or external affairs. If the members of the Iroquois nation were to strive to form a sovereign state in the effort to preserve their identity as a people, they would be exhibiting a kind of nationalism.

Nationalism has long been ignored as a topic in political philosophy, written off as a relic from bygone times. It has only recently come into the focus of philosophical debate, partly in consequence of rather spectacular and troubling nationalist clashes, like those in Rwanda, former Yugoslavia and former Soviet republics. The surge of nationalism usually presents a morally ambivalent, and for this reason often fascinating, picture. ‘National awakening’ and struggle for political independence are often both heroic and inhumanly cruel; the formation of a recognizably national state often responds to deep popular sentiment, but can and does sometimes bring in its wake inhuman consequences, including violent expulsion and ‘cleansing’ of non-nationals, all the way to organized mass murder. The moral debate on nationalism reflects a deep moral tension between solidarity with oppressed ethnic national groups on the one hand and the repulsion people feel in the face of crimes perpetrated in the name of nationalism on the other. Moreover, the issue of nationalism points to the wider domain of problems, having to do with the treatment of ethnic and cultural differences within democratic polity, which are arguably among the most pressing problems of contemporary political theory.

In this entry we shall first present conceptual issues of definition and classification (Sections 1 and 2), and then the arguments put forward in the moral debate (Section 3), dedicating more space to the arguments in favor of nationalism, than to those against it, in order to give the philosophical nationalist a

proper hearing.

---

1. What is a Nation?

1.1 The Basic Concept of Nationalism

Although the term ‘nationalism’ has a variety of meanings, it centrally encompasses the two phenomena noted at the outset: (1) the attitude that the members of a nation have when they care about their identity as members of that nation and (2) the actions that the members of a nation take in seeking to achieve (or sustain) some form of political sovereignty. (See, for example, Nielsen 1998-9, 9.) Each of these aspects requires elaboration. (1) raises questions about the concept of nation or national identity, about what it is to belong to a nation, and about the degree of care about a nation required. Nations and national identity may be defined in terms of common origin, ethnicity, or cultural ties, and while an individual's membership in the nation is often regarded as involuntary, it is sometimes regarded as voluntary. The degree of care for one's nation that is required by nationalists is often, but not always, taken to be very high: on such views one's nation's claims have supremacy in competition with rival contenders for authority and loyalty (see Berlin 1979, Smith 1991, Levy 2000).

(2) raises questions about the whether sovereignty entails the acquisition of full statehood with complete authority for domestic and international affairs, or whether something less than statehood would suffice. Although sovereignty is often taken to mean full statehood (Gellner 1983, ch. 1), more recently possible exceptions have been recognized (Miller 1992, 87).

Despite these definitional worries, there is a fair amount of agreement about what is historically the most typical, paradigmatic form of nationalism. It is the one which features the supremacy of the nation's claims over other claims to individual allegiance, and which features full sovereignty as the persistent aim of its political program. Nationalists often see the state as a political unit centrally `belonging' to one ethnic-cultural group, and actively charged with protecting and promulgating its traditions. This form is exemplified by the classical, ‘revivalist’ nationalism, most prominent in the 19th century in Europe and Latin America. This classical nationalism later spread across the world, and in present days still marks many contemporary nationalisms.

Thus, in its general form, the concept of nationalism concerns the relationship between the ethno-cultural domain (featuring etho-cultural groups or ‘nations’) and the domain of political organization. In our preliminary analysis of the concept, we noted that nationalism involves the attitude that the members of a nation have when they care about their national identity. We can divide the questions raised above in connection with this analysis into two sorts. First, the descriptive ones:

> (1a) What is a nation and national identity?
> (1b) What is it to belong to a nation?
> (1c) What is the nature of a pro-national attitude?
> (1d) Is membership in a nation voluntary or non-voluntary?

Second, the normative ones:

> (1e) Is the attitude of caring about national identity always appropriate?
> (1f) How much should one to care?

In the remainder of this section, we discuss the descriptive questions (1a) -- (1d). We leave questions (1e) and (1f) for Section 3, which concerns the moral debate.

1.2 The Concept of Nation

If one wants to enjoin people to struggle for their national interests, one must have some idea about what a nation is and what it is to belong to a nation. So, in order to formulate and ground their evaluations, claims, and directives for action, pro-nationalist thinkers have been elaborating theories of ethnicity, culture, nation and state. Their opponents have in their turn challenged these theories. Now some presuppositions about ethnic groups and nations are essential for the nationalist, while others are theoretical elaborations designed to support the essential ones. The former concern the definition and status of the target or social group which is the beneficiary of the nationalist program, variously called ‘nation’, ‘ethno-nation’ or ‘ethnic-group’. Since nationalism is particularly prominent with groups that don't yet have a state, one can't define belonging to a nation in terms of belonging to a state.

Indeed, purely ‘civic’ loyalties are often put into the separate category under the title ‘patriotism’, or ‘constitutional patriotism’ (Habermas 1996). This yields a spectrum of definitions for the concept of

‘nation’, with lots of intermediate positions. On one end of the spectrum, we find a small but distinguished band of theorists, including E. Renan (1882) and M. Weber (1970). Recall that on their definition, a nation is any group of people who voluntarily aspire to a common political state-like organization. Recall also that if such a group of people succeeds in forming a state, the loyalties of the group members would be ‘civic’ (as opposed to ‘ethnic’) in nature. The other end of the spectrum is more typical, for nationalist claims are focused upon a community of common origin, language, tradition and culture, membership in which is non-voluntary. Thus, on this more typical view, an ethno-nation is a community of origin and culture, including prominently a language and customs.

The distinction between these two distinct concepts of nationhood is related (although not identical) to the one drawn by older schools of social and political science between ‘civic’ and ‘ethnic’ nationalism, the first being allegedly Western European and the later more Central and Eastern European originating in Germany (a very prominent proponent of the view is H. Kohn 1965). Philosophical discussions centered around nationalism tend to concern the ethnic-cultural variants only and this habit will be followed here. A group aspiring to nationhood on this basis will be called here an ‘ethno-nation’ in order to underscore its ethno-cultural rather than purely civic underpinnings. For the ethno-(cultural) nationalist it is one’s ethnic-cultural background which determines one’s membership in the community. One can't choose to be a member; instead, membership depends on the accident of origin and early socializing. It may be, however, that commonality of origin is an almost mythical notion for most contemporary candidate groups: ethnic groups have been mixing for millennia.

Therefore, sophisticated pro-nationalists tend to stress cultural membership only, and speak of ‘nationality’, omitting the ‘ethno-’ part (Miller 1992, 87; Tamir 1993). M. Seymour in his recent proposal of a ‘socio-cultural definition’ adds a political dimension to the purely cultural one. A nation is a cultural group, possibly but not necessarily united by a common descent, endowed with some kind of civic ties (Seymour 2000). This is the kind of definition that would be accepted by most parties in the debate today. So defined, nation is a somewhat mixed, both ethno-cultural and civic category, but still closer to the purely ethno-cultural than to the purely civic extreme.

The wider descriptive underpinning of nationalist claims has varied across the last two centuries. The early German discussions feature talk about ‘the spirit of people’, while somewhat later ones, mainly of French extraction, about ‘collective mentality’, ascribing to them specific and significant causal powers. A later descendent of this notion is the idea of a ‘national character’ peculiar to each nation, which partly survives today under the guise of national ‘forms of life’ and of feeling (Margalit 1997, see below). For almost a century, up to the end of the Second World War, it was customary to link nationalistic views with the metaphor of a society being something ‘organic’. Isaiah Berlin, writing as late as the early seventies, proposed as a part of his definition of nationalism that it consists of the conviction that people belong to a particular human group, and that "...the characters of the individuals who compose the group are shaped by, and cannot be understood apart from, those of the group ..." (first published in 1972, reprinted in Berlin, 1979: 341). The nationalist claims, according to Berlin, that "the pattern of life in a society is similar to that of a biological organism" (*ibid*.), and that the needs of this ‘organism’ determine the supreme goal of all of its members.

Most contemporary defenders of nationalism, especially philosophers, avoid such language. The metaphor of organism and talk about character have been replaced by one master-metaphor -- that of national identity. It is centered upon cultural membership, and used both for the identity of a group and for the socially-based identity of its members, e.g., the national identity of George in so far as he is English or British. Various authors unpack the metaphor in various ways -- some stress involuntary membership in the community, others the strength with which one identifies with the community, yet others link it to the personal identity of each member of the community. Addressing these issues, the nationally minded philosophers, like MacIntyre (1994), Taylor (1989), Seymour and others have significantly contributed to introducing and maintaining important topics such as community, membership, tradition and social identity in contemporary philosophical debate.

Let us now turn to the issue of the origin and 'authenticity' of ethno-cultural groups or ethno-nations. In social and political science one usually distinguishes two kinds of views. The first are the 'primordialist' views. According to them, actual ethno-cultural nations have either existed 'since time immemorial' (an extreme, somewhat caricatured version, corresponding to nineteenth century nationalist rhetoric), or at least for a long time during the pre-modern period (a more moderate version championed by A. Smith (1991)). The second are the modernist views, placing the origin of nations in modern times. They can be further classified according to their answer to a further question: how real is the ethno-cultural nation? The modernist realist view is that nations are real but distinctly modern creations, instrumental in the genesis of capitalism (Gellner 1983, and Hobsbawn 1990). On the opposite side of the fence one finds anti-realist views. According to one such view nations are merely 'imagined' but somehow still powerful entities; what is meant is that belief in them holds sway over the believers (Anderson 1965). The extreme anti-realist view claims that they are pure 'constructions'. These divergent views seem to support rather divergent moral claims involving the concept of a nation.

Indeed, older authors -- from great thinkers like Herder and Bauer, to the propagandists who followed their footsteps -- have been at great pains to ground normative claims upon firm ontological realism about nations: nations are real, *bona fide* entities. However, the contemporary moral debate has tried to diminish the importance of the imagined/real divide. Prominent contemporary philosophers have claimed that normative-evaluative nationalist claims are compatible with the 'imagined' nature of nation. (See, for instance, Miller 1992, Tamir 1993, and MacCormick 1982.) They point out that common imaginings can tie people together, and that actual interaction resulting from togetherness can engender important moral obligations.

Let us now turn to question (1c), concerning the nature of pro-national attitudes. The explanatory issue that has interested political and social scientists concerns ethno-nationalist sentiment, the paradigm case of a pro-national attitude. Is it as irrational, romantic and indifferent to self-interest as it might seem on the surface? The issue has divided authors into two camps -- those who see nationalism as basically irrational and those who try to explain it as being rational at least in some sense. Authors in the first camp propose various explanations of why people assent to irrational views. Some say, critically, that nationalism is based on 'false consciousness'. But where does such false consciousness come from? The most simplistic view is that it is a result of direct manipulation of 'masses' by 'elites'. On the opposite side, the famous critic of nationalism, E. Kedourie (1960) sees this irrationality as being spontaneous.

Authors relying upon the Marxist tradition offer various deeper explanations. To mention one, the French structuralist E. Balibar sees it as a result of 'production' of ideology effectuated by mechanisms which have nothing to do with spontaneous credulity of individuals, but with impersonal, structural social factors (Balibar and Wallerstein 1992).

Consider next the other camp of those who see nationalistic sentiments as being rational at least in some weak sense. Some authors claim that it is often rational for individuals to become nationalists (Hardin 1985). On the one hand, identification and cohesion within the ethno-national group has to do with inter-group cooperation, and cooperation is easier for those who are part of the same ethno-national group. To take an example of ethnic ties in a multiethnic state, a Vietnamese newcomer to the States will do well to rely on his co-nationals: common language, customs and expectations might help him a lot in finding his way in new surroundings. Once the ties are established and he has become part of a network, it is rational to go on cooperating, and ethnic sentiment does secure the trust and the firm bond needed for smooth cooperation. A further issue is when it is rational to switch sides; to stay with our example, when does it become profitable for our Vietnamese to develop an all-American patriotism. This has received a detailed elaboration in Laitin (1998), who uses material from the ex-Soviet Union. On the other hand, there is conflict between various ethno-nations which leads to non-cooperation with outsiders. Can one rationally explain the extremes of ethno-national conflict? Authors like Hardin propose to do it in terms of a general view of when a hostile behavior is rational: most typically, if you have no reason to trust someone, it is reasonable to take precautions against him. If both sides take precautions, however, each will tend to see the other as being seriously inimical. It then becomes rational to start treating the other as an enemy. Mere suspicion can thus lead by small, individually rational steps, to a situation of conflict. (Such negative development is often presented as a variant of the so-called Prisoner's Dilemma.) Now, it is relatively easy to spot the circumstances in which this general pattern applies to national solidarities and conflicts. The line of thought just sketched is often called 'rational choice approach'. It has enabled the application of conceptual tools from game-theoretic and economic theories of cooperative and non-cooperative behavior for explanation of ethno-nationalism.

It is worth mentioning, however, that the individualist rational-choice approach, centered upon personal rationality, has serious competitors. A tradition in social psychology, initiated by Tajfel (1981), shows that individuals may identify with a randomly selected group, even when membership in the group brings no tangible rewards. Does rationality of any kind underlie this tendency of identification? Some authors (Sober & Wilson 1998) answer in the affirmative. They propose that it is a non-personal, evolutionary rationality: individuals who develop a sentiment of identification and sense of belonging end up better off in the evolutionary race, and that is why we have inherited such propensities. The initial sentiments were reserved for one's own kin, thus supporting the spreading of one's own genes. Cultural evolution has taken over the mechanisms of identification that initially developed within biological evolution. As a result, we project the sentiment originally reserved for kinship to our cultural group. Further, detailed explanations in such socio-biological perspective differ a lot among themselves, and constitute a wide research program.

Finally, concerning question (1d), a nation is typically seen as essentially a non-voluntary community to which one belongs by birth and early nurture, whereby the relation of belonging is somehow enhanced

and perhaps taken to a higher level, becoming more conscious and more complete by one's additional endorsement. (There are exceptions to this basically non-voluntaristic view, for instance, theoretical nationalists who accept voluntary changes of nationality. See also E. Renan's (1882, 19) famous definition of a nation as constituted by 'everyday plebiscite'.)

2. Varieties of Nationalism

2.1 Concepts of Nationalism: Strict and Wide

Recall again our basic analysis, namely, that nationalism involves (1) the attitude that the members of a nation have when they care about their national identity, and (2) the actions that the members of a nation take when seeking to achieve (or sustain) some form of political sovereignty. The politically central point is (2), the actions enjoined by the nationalist. This point raises three important questions:

(2a) Does political sovereignty require statehood or something weaker?
(2b) What actions are appropriate to bringing sovereignty about and maintain it?
(2c) Under what conditions is it appropriate to take actions of this kind?

To these we now turn.

The classic (and conservative) answer to (2a) is that political sovereignty requires statehood, while the more liberal answer is that some form of political autonomy is required, though not necessarily full statehood. Consider the former, classic answer to (2a).

On this view, political sovereignty requires a state 'rightfully owned' by the ethno-nation (Oldenquist, 1997, who credits the expression to the writer C. Milosz). However, this classic form of nationalism is not only concerned with the creation of a state but also with its maintenance and strengthening. Once the state is there, further options are opened for nationalists. They sometimes promote claims for its expansion (even at the cost of wars) and sometimes opt for isolationist policies. The expansion is often justified by appeal to the unfinished business of bringing literally *all* members of the nation under one state, and sometimes justified simply as an interest the nation has in gaining more territory and resources. In doing this they often imply specific answers to (2b) and (2c), i.e., that in national independence struggle the use of force is almost always a legitimate means for bringing about sovereignty. As for maintenance of sovereignty by peaceful and merely ideological means, political nationalism is closely tied to nationalism in culture. The latter insists upon the preservation and transmission of a given culture, more accurately, of recognizably ethno-national traits of the culture in its pure form, dedicating artistic creation, education and research to this goal. Of course, the ethno-national traits can be actual or invented, partly or fully so. Again, in the classical variant the relevant norm claims that one has both a right and an obligation ('a sacred duty') to promote such traditions. Its force is that of a trump that wins over other interests and even over human rights (and this trump is often needed in order to carry on

national independence struggle).

As a consequence, this classic form of nationalism has something to say about the level of attitudes as well. It answers question (1e) affirmatively, and sees caring for one's nation as a fundamental duty of each of its members. It is also prone to give, in its answer to (1f), an unlimited scope. We can now summarize this classic form of nationalism as follows:

> **Classical nationalism** is the political program that seeks the creation and maintenance of a fully sovereign state owned by a given ethno-national group ('people' or 'nation') and that sees the creation and maintenance of this state as a primary duty of each member of the group. Starting from the assumption that the appropriate (or 'natural') unit of culture is ethno-nation, classical nationalism involves the claim that a primary duty of each member is to abide in cultural matters by one's recognizably ethno-national culture.

Classical nationalists are usually quite watchful about the kind of culture they protect and promote, and about the kind of attitude people have to their nation-state. This watchful attitude carries some potential dangers -- many elements of a given culture which are universalist or simply not recognizably national might, and will sometimes, fall prey to such nationalist enthusiasms. Classical nationalism in everyday life puts various additional demands on individuals, from buying more expensive home-produced goods in preference to the cheaper imported ones, to procreating as many future members of the nation as one can manage. (See Yuval-Davies 1997.)

The more liberal answer to question (2a), that some form of political automony less than full statehood is required to achieve nationalist goals, yields more moderate forms of nationalism. Indeed, the philosophical discussion has shifted to these moderate or even ultra-moderate forms, and most philosophers who describe themselves as nationalists propose very moderate nationalist programs. These more moderate forms involve weaker claims than the classic form, along a variety of dimensions. Indeed, a wider concept of nationalism is needed to accomodate the wide variety more moderate forms. Let us therefore define:

> **Nationalism in the wide sense** is any complex of attitudes, claims and directives for action which ascribe a fundamental political, moral and cultural value to nation and nationality and which produce obligations (for individual members of the nation, and for any involved third parties, individual or collective) on the basis of this ascribed value.

Different forms of nationalism in this larger sense result when we vary the concept of nation involved, vary the ground and degree of its value, vary the scope of claims for action and of the prescribed obligations. (This wider concept of nationalism can also be applied to other cases not covered by classical nationalism, for instance, the hypothetical pre-state political forms that an ethnic identity might take). Moderate nationalism is a form of nationalism in the wider sense which is less demanding than classical nationalism. It sometimes goes under the name of 'patriotism'. (A different usage, though, reserves 'patriotism' for valuing the civic community and loyalty to the state, in contrast to nationalism,

which is centered around ethnic-cultural communities.) The various forms of nationalism most relevant for philosophy are those that influence the moral standing of claims for action and of recommended nationalist practices. The elaborate philosophical views put forward in favor of nationalism will be referred to here to as ‘theoretical nationalism’, the adjective serving to distinguish such views from the less sophisticated and more practical nationalist discourse. The central theoretical nationalist evaluative claims can usefully be put on the map of possible positions within political theory in the following somewhat simplified and schematic way.

Nationalistic claims featuring the centrality of nation for political action provide an answer to two crucial general questions. First, is there one kind of large social group (smaller than the whole of mankind) that is morally of central importance or not? The nationalist answer is that there is just one, namely, the nation. When an ultimate choice is to be made, nation has priority. (This answer is implied by rather standard definitions offered by Berlin and Smith.) Second, what is the ground of obligation that the individual has to the morally central group? Is it voluntary or involuntary membership in the group? The typical contemporary nationalist thinker answers by the latter, while admitting that voluntary endorsement of one’s national identity is a morally important achievement. On the philosophical map, the pro-nationalist normative tastes fit nicely with the communitarian stance in general: most pro-nationalist philosophers are communitarians who choose nation as the preferred community (in contrast to those of their fellow-communitarians who prefer more far-ranging communities, such as those defined by global religious traditions). However, some recent writers, e.g., Kymlicka (2001), who describe themselves as liberal nationalists, reject the communitarian underpinning.

2.2 Moral Claims: The Centrality of Nation

We now prepare the ground for the discussion of the normative dimension of nationalism. We shall first describe the very heart of the nationalist program, i.e., sketch and classify the typical normative and evaluative nationalist claims. These claims can be seen as answers to the normative subset of our initial questions about (1) pro-national attitudes and (2) actions.

The claims thus recommend various courses of action, centrally those meant to secure and sustain the political organization -- preferably a state -- for the given ethno-cultural national community, thereby making more specific the answers to our normative questions (1e), (1f), (2b) and (2c). Further, they enjoin the members of the community to promulgate recognizable ethno-cultural values, artifacts, and traditions as central features of the cultural life within such a state. Finally, we shall discuss various lines of pro-nationalist thought that have been put forward in defense of these claims. Let us begin with the claims which concern the furthering of the national state and culture. They are proposed by the nationalist as a guide and a norm of conduct. Philosophically the most important variations concern three aspects of such normative claims. They are as follows:

(i) *The normative nature and strength of the claim*. Does it promote just a right (say, to having and maintaining a form of political self-government, preferably and typically a state, or having the cultural life centered upon recognizably ethno-national culture), or a moral obligation (to get and maintain one),

or a legal and political obligation? These differences can be described in professional terminology as variations in the ‘non-comparative deontic status’ of central claims. The strongest claim is typical for the classical nationalism: its norms are both moral imperatives and, once the nation-state is in place, legally enforceable obligations in regard to all parties concerned, including the individual members of the ethno-nation. A weaker, but still quite demanding version speaks only of moral obligation (‘sacred duty’). A more liberal version is satisfied simply with a right to having a state that would be ‘owned’ by the ethno-nation.

(ii) *The strength of the nationalistic claim in relation to various external interests and rights*. To give a real example, is the use of the domestic language so important that even international conferences should be held in it, at the cost of losing the most interesting participants from abroad? Since the force of the nationalist claim is here being weighed against the force of other claims, those of individual or group interests, or rights, one can call this dimension the ‘comparative deontic status’ of the claim. Variations in comparative deontic status take place on a continuum between two extremes. On one rather nasty extreme the nation-focused claims are seen as trumps that take precedence over any other claims, even over human rights. Further towards the center is the classical nationalism that gives nation-centered claims precedence over the interests and needs of the individual (including pragmatic collective utility), but not necessarily over general human rights. (See, for example, McIntyre 1994, Oldenquist, 1997.) On the opposite end, which is mild, humane and liberal, the central nationalistic claims are accorded *prima facie* status only (see Tamir, 1993).

(iii) *For which groups are the nationalist claims meant to be valid, what is their scope?* First, they can be valid for every ethno-nation and thereby universal. An example would be the claim "every ethno-nation should have its own state". To put it more formally, we have:

> **Universalist nationalism** is the political program that claims that *every* ethno-nation should have its state which it should rightfully own, and whose interests it should promote.

Alternatively, a claim may be more particular, such as the claim "Group *X* ought to have a state", where this implies nothing about any other group:

> **Particularist nationalism** is the political program that claims that *some* ethno-nation should have its state, without extending the claim to all ethno-nations. It does this either
>
> > (A) by omission (unreflective particularist nationalism), or
> >
> > (B) by explicitly specifying who is excluded: "Group *X* ought to have a state, but group *Y* should not" (invidious nationalism).

We have called the most difficult (and indeed chauvinistic) sub-case of particularism, i.e., (B), ‘invidious’ since it explicitly denies the privilege of having a state to some peoples. T. Pogge (1997) proposes a further division of (B) into the ‘high’ stance which denies statehood to some types of peoples,

and the ‘low’ one which denies it to some particular peoples. Serious theoretical nationalists usually defend only the universalist variety, whereas the nationalist-in-the-street most often defends the particularist one (‘Some nations should have a state, above all mine!’). Classical nationalism comes both in particularist and universalist varieties.

Although the three dimensions of variation described above -- (i) internal deontic status, (ii) external deontic status, and (iii) scope -- are logically independent, they are psychologically and politically intertwined. People who are radical in one respect on the nationality issue tend also to be radical in other respects. In other words, attitudes tend to cluster together in stable clusters, so that extreme (or moderate) attitudes on one dimension psychologically and politically belong with extreme (or moderate) ones on others. The hybrids of extreme attitude on one dimension with moderate on the others are psychologically and socially unstable.

3. The Moral Debate

3.1 Classical and Liberal Nationalisms

Recall our initial analysis, centered around (1) attitudes and (2) actions. Is national partiality justified and to what extent? What actions are appropriate to bringing sovereignty about? In particular, are ethno-national states and institutionally protected (ethno-) national cultures goods independent from the individual will of the members, and how far may one go in protecting them? The philosophical debate for and against nationalism is the debate about the moral validity of its central claims. In particular the ultimate moral issue is the following: is any form of nationalism morally permissible or justified, and, if not, how bad are particular forms of it?

Why do nationalist claims require a defense? In some situations they seem very plausible; for instance the plight of some stateless national groups -- the history of Jews and Armenians, the misfortunes of Kurds -- makes one spontaneously endorse the idea that if these groups had had their own state, serious problems would have been avoided. Still, there are good reasons to examine the general nationalist claims. The most general reason is that it should first be shown that the nation as such has some value and that claims in its favor have some normative validity. Once this is established, a further defense is needed. Some classical nationalist claims appear to clash -- at least under normal circumstances of contemporary life -- with various values that people tend to accept. Some of these values are considered essential to liberal-democratic societies, while others are important specifically for the flourishing of culture and creativity. The main values in the first set are individual autonomy and benevolent impartiality (most prominently towards members of groups culturally different from one's own). The alleged special duties towards one's ethno-national culture can interfere, and often do interfere, with individuals’ right to autonomy. Also, if these duties are construed very strictly they can interfere with other individual rights, e.g., the right to privacy. Many feminist authors have noted that a suggestion typically offered by the nationalist, namely that women have a moral obligation to give birth to new members of the nation and to nurture them for the sake of the nation, clashes both with autonomy and

privacy of these women (Yuval-Davis 1997). Another endangered value is diversity within ethno-national community, which can also be thwarted by the homogeneity of a central national culture.

The nation-oriented duties also interfere with the value of unconstrained creativity, e.g., telling writers or musicians or philosophers that they have a special duty to promote national heritage interferes with the freedom of creation. (The question here is not whether these individuals have the right to promote their national heritage, but whether they have a duty to do so.)

In between these two sets of endangered values, the autonomy-centered and creativity-centered ones, are the values that seem to arise from ordinary needs of people living under ordinary circumstances. In many modern states citizens of different ethnic background live together, and very often value this kind of life. This very fact of cohabitation seems to be a good that should be upheld. Nationalism does not tend to foster this kind of multiculturalism and pluralism, judging from both theory (especially the classical nationalist one) and experience. But the problems get worse. In practice, a rather widespread variant of nationalism is the invidious particularist form claiming rights for one's own people and denying them to others, for reasons that seem to be far from accidental. The source of the problem is the competition for scarce resources; as Gellner (1983) has famously pointed out, there is too little territory for all candidate ethnic groups to have a state and the same goes for other goods demanded by nationalists for the exclusive use of their co-nationals. According to some authors (McCabe 1997) the invidious variant is more coherent than any other form of nationalist; if one values highly one's own ethnic group the simplest way is to value it *tout court*. If one definitely prefers one's own culture in all respects to any foreign one, it is a waste of time and attention to bother about others. The universalist, non-invidious variant introduces enormous psychological and political complications. They arise from a tension between spontaneous attachment to one's own community and the demand to regard all communities with an equal eye. This tension might make the humane, non-invidious position psychologically unstable, and hard to uphold in situations of conflict and crisis. This psychological weakness renders it politically less efficient.

The philosophical authors sympathetic to nationalism are aware of the evils that historical nationalism has produced, and usually distance themselves from them. They usually speak of "various accretions that have given nationalism a bad name," and they are eager to "separate the idea of nationality itself from these excesses" (Miller 1992, 87). Such thoughtful pro-nationalist writers have put forward several lines of thought in defense of such a nationalism, thereby initiating an ongoing philosophical dialogue between the proponents and the opponents of the claim (see the anthologies McKim & McMahan 1997, Couture, Nielsen, & Seymour 1998, and Miscevic 2000). In order to help the reader find his or her way through the rather involved debate, we shall briefly summarize the considerations which are open to the ethno-nationalist to defend his or her case. (Compare the useful overview in Lichtenberg 1997.) The considerations and lines of thought built upon them can be used to defend very different varieties of nationalism, from radical to very moderate ones.

It is important to offer a warning concerning the key assumptions and premises which figure within each of the lines of thought summarized below, namely, that the assumptions often live an independent life in the philosophical literature. Some of them figure in the proposed defenses of various traditional views

which have little to do with the concept of nation in particular.

For brevity, I shall reduce each line of thought to a brief argument (these arguments will be listed and discussed in Sections 3.2 and 3.3). The actual debate is, however, more involved than one can represent in a sketch. I shall sometimes indicate, in brackets, some prominent lines of criticism that have been put forward in the debate. (These are discussed in greater detail in Miscevic 2001.) The main arguments in favor of nationalism, which purport to establish its fundamental claims about state and culture, will be divided into two sets. The first set of arguments (listed in Section 3.2) defend the claim that national communities have a high value, often seen as non-instrumental and independent of the wishes and choices of their individual members, and argue that therefore they should be protected by means of state and official statist policies. The second set (listed in Section 3.3) is less deeply ‘philosophical’ (or ‘comprehensive’), and encompasses arguments from requirements of justice which are rather independent of substantial assumptions about culture and cultural values.

The first set will be presented here in more detail, since it has formed the center of the debate. The arguments in this set depict the community as the source of value or as the unique transmission device that connects the members to some important values. In this sense, the arguments from this set are communitarian in the ‘deep’ sense of being grounded in basic features of the human condition. Here is a characterization.

> The **deep communitarian perspective** is a theoretical perspective on political issues which justifies a given political arrangement (e.g., a nation-state) by appeal to philosophical assumptions about human nature, language, community ties and identity (in the philosophical sense).

The general form of the arguments in the first set is the following. First, the deep communitarian premise: there is some uncontroversial good (e.g., a person's ethnic identity), and some kind of community is essential for acquisition and preservation of it. Then comes the claim that ethno-cultural nation is the kind of community ideally suited for this task. Unfortunately, this crucial claim is rarely defended in detail in the literature. But here is a sample from Avishai Margalit:

> The idea is that people make use of different styles to express their humanity. The styles are generally determined by the communities to which they belong. There are people who express themselves ‘Frenchly’, while others have forms of life that are expressed ‘Koreanly’ or ... ‘Icelandicly’. (Margalit 1997, 80)

The argument ends with the statist conclusion: in order that such a community should preserve its own identity and support the identity of its members, it has to assume (always or at least normally) the political form of a state. The conclusion of this type of argument is that the ethno-national community has the right, in respect to any third party and to its own members, to have an ethno-national state, and the citizens of the state have the right and obligation to favor their own ethnic culture in relation to any other.

Although the philosophical assumptions in the arguments stem from the communitarian tradition, weakened forms have also been proposed by more liberally-minded philosophers. The original communitarian lines of thought in favor of nationalism suggest that there is some value in preserving ethno-national cultural traditions, in feelings of belonging to a common nation and in solidarity between its members. A liberal nationalist might accept that these may not be the central values of political life, but claim that they are values nevertheless. Moreover, the diametrically opposite views, pure individualism and cosmopolitanism, do seem arid and abstract, and may appear unmotivated. Compare, for example, the notion of cosmopolitanism:

> **Cosmopolitanism** is the moral and political doctrine which asserts that (a) one's primary moral obligations are directed to all human beings (regardless of geographical or cultural distance), and (b) political arrangements should faithfully reflect this universal moral obligation (in the form of supra-statist arrangements that take precedence over nation-states).

Confronted with these opposite pulls, many philosophers opt for a mixture of liberalism-cosmopolitanism and patriotism-nationalism. B. Barber in his writings glorifies "a remarkable mixture of cosmopolitanism and parochialism" which, in his view characterizes American national identity (in Cohen 1996, 31). Charles Taylor claims that "we have no choice but to be cosmopolitan and patriots" (*ibid*., 121). Hilary Putnam proposes loyalty to what is best in the multiple traditions that each of us participates in; apparently a middle way between a narrow-minded patriotism and a too abstract cosmopolitanism (*ibid*., 114). The compromise has been foreshadowed by Berlin (1979) and Taylor (1989, 1993), and its various versions worked out in considerable detail by authors such as Tamir (1993), Miller (1995), Nielsen (1998) and Seymour. In recent years it occupies the center stage of the debate. Most liberal nationalist authors accept various weakened versions of the arguments we list below, taking them to support moderate or ultra-moderate nationalist claims.

Here are the main weakenings of classical ethno-nationalism that the liberal, limited-liberal and cosmopolitan nationalists propose. First, ethno-national claims have only *prima facie* strength, and cannot trump individual rights. Second, legitimate ethno-national claims do not, in themselves and automatically, amount to a right to having a state, but rather a right to have a certain level of cultural autonomy. Third, ethno-nationalism is subordinate to civic patriotism, and this has little or nothing to do with ethnic criteria. Fourth, ethno-national mythologies and similar ‘important falsehoods’ are to be tolerated only if benign and inoffensive, in which case they are morally permissible in spite of their falsity. Finally, any legitimacy that ethno-national claims may have is to be derived from the choices the concerned individuals should be free to make.

3.2 Arguments in Favor of Nationalism: The Deep Need for Community

Consider now the particular arguments from the first set. The first argument depends on assumptions that

also appear in the subsequent ones, but whereas it ascribes to the community an intrinsic value, the following ones point more towards an instrumental value of a nation which is derived from the value of individual flourishing, moral understanding, firm identity and the like.

(1) *The Argument From Intrinsic Value*. Each ethno-national community is valuable in and of itself, since it is only within the natural encompassing framework of various cultural traditions that important meanings and values are produced and transmitted. The members of such communities share a special cultural proximity to each other. By speaking the same language and sharing customs and traditions, the members of these communities are typically closer to one another in various ways than they are to those who don't share the culture. The community thereby becomes a network of morally connected agents, i.e., a moral community, with special, very strong ties of obligation. A prominent obligation of each individual concerns the underlying traits of the ethnic community, above all language and customs: they ought to be cherished, protected, preserved and reinforced. (The general assumption that moral obligations increase with cultural proximity is often criticized as problematic. Moreover, even if we grant this general assumption in theory, it breaks down in practice. Nationalist activism is most often turned against close (and, in many respects, similar) neighbors rather than against distant strangers, so that in many important contexts the appeal to proximity will not work. It might retain its potential force against culturally distant groups, however.)

(2) *The Argument From Flourishing*. The ethno-national community is essential for each of its members to flourish. In particular, it is only within such a community that an individual can acquire concepts and values crucial for understanding the community’s cultural life in general and one’s own life in particular. There has been a lot of debate on the pro-nationalist side about whether divergence of values is essential for separateness of national groups. Canadian liberal nationalists, Seymour (1999), Taylor, and Kymlicka, pointed out that the ‘divergences of values between different regions of Canada’ that aspire to separate nationhood are ‘minimal’. Taylor (1993, 155) concluded that it is not separateness of value that matters. This result is still compatible with the argument from flourishing, if ‘concepts and values’ are not taken to be specifically national, as communitarian nationalists (MacIntyre 1994, Margalit 1997) have claimed.

(3) *The Argument From Moral Understanding*. A particularly important variety of value is moral value. Some values are universal, but they are too abstract and ‘thin’. The rich, ‘thick’ moral values are discernible only within particular traditions, to those who have wholeheartedly endorsed the norms and standards of the given tradition. As Charles Taylor puts it, ‘the language we have come to accept articulates the issues of the good for us’ (1989, 35). The nation offers a natural framework for moral traditions, and thereby for moral understanding; it is the primary school of morals. (I note in fairness that Taylor himself is ambivalent about the national format of morality. An often noticed problem for this line of thought is that particular nations do not each have a special morality of their own. Also, the detailed, ‘thick’ morality may vary more across other divisions, such as class or gender divisions, than across ethno-national groups.)

(4) *The Argument from Identity*. Communitarian philosophers emphasize nurture over nature as the principal force determining our identity as persons -- we come to be the persons we are because of the

social settings and contexts in which we mature. The claim certainly has some plausibility. The very identity of each person depends upon his/her participation in communal life (see MacIntyre 1994, Nielsen, 1998, and Lagerspetz 2000). For example, Nielsen writes:

> We are, to put it crudely, lost if we cannot identify ourselves with some part of an objective social reality: a nation, though not necessarily a state, with its distinctive traditions. What we find in people -- and as deeply embedded as the need to develop their talents -- is the need not only to be able to say what they can do but to say who they are. This is found, not created, and is found in the identification with others in a shared culture based on nationality or race or religion or some slice or amalgam thereof. ... Under modern conditions, this securing and nourishing of a national consciousness can only be achieved with a nation-state that corresponds to that national consciousness. (1993, 32)

Given that an individual's morality depends upon their having a mature and stable personal identity, the communal conditions which foster the development of such personal identity have to be preserved and encouraged. The philosophical nationalists claim that the national format is the right format for preserving and encouraging such identity-providing communities. Therefore, communal life should be organized around particular national cultures. The classical nationalist proposes that cultures should be given their states, while the liberal nationalist proposes that cultures should get at least some form of political protection.

(5) *The Argument from Diversity*. Each national culture contributes in a unique way to the diversity of human cultures. The most famous contemporary proponent of the idea, Isaiah Berlin (interpreting Herder, who first saw this idea as significant) writes:

> The ‘physiognomies’ of cultures are unique: each presents a wonderful exfoliation of human potentialities in its own time and place and environment. We are forbidden to make judgments of comparative value, for that is measuring the incommensurable. (1976, 206)

The carrier of basic value is thus the totality of cultures, from which each national culture and style of life that contributes to the totality derives its own value. The plurality of styles can be preserved and enhanced by tying the styles to ethno-national ‘forms of life’. The argument from diversity is therefore pluralistic: it ascribes value to each particular culture from the viewpoint of the totality of cultures available. Assuming that the (ethno-) nation is the natural unit of culture, the preservation of cultural diversity amounts to institutionally protecting the purity of (ethno-) national culture. (A pragmatic inconsistency might be threatening this argument. The issue is who can legitimately propose nationhood: the nationalist is much too tied to his or her own culture to do it, while the cosmopolitan is too eager to preserve intercultural links that go beyond the idea of having a single nation-state. Moreover, is diversity a value such that it deserves to be protected whenever it exists?)

The lines of thought in the set of arguments just presented are all linked to the importance of community life in relation to the individual. They emerged from the perspective of ‘deep’ communitarian thought,

and a recurrent theme is the importance of the fact that membership in the community is not chosen but rather involuntary. As noted previously, each argument involves a general communitarian premise (a community, to which one has no choice whether or not to belong, is crucial for one's identity, or for flourishing or for some other important good). This premise is coupled with the more narrow nation-centered descriptive claim that the ethno-nation is precisely the kind of community ideally suited for the task. However, liberal nationalists do not find these arguments completely persuasive. In their view, the premises of the arguments may not support the full package of nationalistic ambitions, and may not be unconditionally valid. Still, there is a lot to these arguments, and they might support liberal nationalism and a more modest stance in favor of national cultures.

The liberal nationalist stance is mild and civil, and there is lot to be said in its favor. It strives to reconcile our intuitions in favor of some sort of political protection of cultural communities, with a liberal political morality. Of course, this raises issues of compatibility between liberal universal principles and the particular attachments to one’s ethno-cultural nation. Very liberal nationalists such as Tamir divorce ethno-cultural nationhood from statehood. Also, the kind of love for country they suggest is tempered by all kinds of universalist considerations, which in the last instance trump national interest (Tamir 1993, 115). There is an ongoing debate among philosophical nationalists about how much weakening and compromising is still compatible with a stance’s being nationalist at all. (For example, Canovan 1996 (ch. 10) presents Tamir as abandoning the ideal of ‘nation-state’, and thereby nationhood as such; Seymour (1999) criticizes Taylor and Kymlicka for turning their backs on genuine nationalistic programs, and proposing multiculturalism instead of nationalism.) There is also a streak of cosmopolitan interest present in the work of some liberal nationalists (Nielsen (1998/9).

3.3 Arguments in Favor of Nationalism: Issues of Justice

The arguments in the second set concern political justice and do not rely on metaphysical claims about identity, flourishing and cultural values. They appeal to (actual or alleged) circumstances which would make nationalistic policies reasonable (or permissible or even mandatory), such as (a) the fact that a large part of the world is organized into nation states (so that each new group aspiring to create a nation-state just follows an established pattern), or (b) the circumstances of group self-defense or of redress of past injustice which might justify nationalist policies (to take a special case). Some of them also present nationhood as conducive to important political goods, such as equality.

(1) *The Argument From the Right to Collective Self-determination*. A group of people of a sufficient size has a *prima face* right to govern itself and decide its future membership, if the members of the group so wish. It is fundamentally the democratic will of the members themselves that grounds the right to an ethno-national state and to ethno-centric cultural institutions and practices. This argument presents the justification of (ethno-) national claims as deriving from the will of the members of the nation. It is therefore highly suitable for liberal nationalism and not very interesting for a deep communitarian, who sees the demands of the nation as being independent from, and prior to, the choices of particular individuals. (For extended discussion of this argument, see Moore 1998.)

(2) *The Argument From the Right to Self-defense and to Redress Past Injustices*. Oppression and injustice give a victimized group a just cause and the right to secede. If a minority group is oppressed by the majority, so that almost every minority member is worse off than most majority ones, simply in virtue of belonging to the minority, then the nationalist minority claims are morally plausible, and may even be compelling. The argument implies a very restrictive answer to our questions (2b) and (2c): the use of force in order to achieve sovereignty is legitimate only in the cases of self-defense and redress. It establishes a typical remedial right, which is acceptable from a liberal standpoint. (See a recent discussion in Kukathas and Poole 2000.)

(3) *The Argument From Equality*. Members of a minority group are often disadvantaged in relation to a dominant culture because they have to rely on those with the same language and culture to conduct the affairs of daily life. Since freedom to conduct one's daily life is a primary good, and it is difficult to change or give up reliance on one's minority culture to attain that good, this reliance can lead to certain inequalities if special measures are not taken. Spontaneous nation-building by the majority has to be moderated. Therefore, liberal neutrality itself requires that the majority provide certain basic cultural goods, i.e., granting differential rights. (See Kymlicka 1995b.) Institutional protections and the right to the minority group's own institutional structure are remedies that restore equality and turn the resulting nation-state into a more moderate multicultural one. (See Kymlicka 2001.)

(4) *The Argument From Success*. The nation-state has been successful in the past, promoting equality and democracy. The ethno-national solidarity is a powerful motive for a more egalitarian distribution of goods (Miller 1995, Canovan, 1996). The nation-state also seems to be essential to safeguard the moral life of communities in the future, since it is the only form of political institution capable of protecting communities from the threats of globalization and assimilationism. (For a detailed critical discussion of this argument see Mason 1999.)

These political arguments can be combined with deep communitarian ones. However, taken in isolation, they offer the more interesting perspective of a ‘liberal culturalism’ that is more suitable for ethnically and culturally plural societies. It is more remote from classical nationalism than the liberal nationalism of Tamir and Nielsen, since it eschews any communitarian philosophical underpinning (see the detailed presentation and defense in Kymlicka 2001, who still occasionally calls such culturalism ‘nationalistic’). The idea of moderate nation-building points to an open multi-culturalism, in which every group receives its share of remedial rights, but instead of walling itself up against others, participates in a common, overlapping civic culture in open communication with other sub-communities. Given the variety of pluralistic societies, and intense trans-national interactions, such openness seems to many to be the only guarantee of stable social and political life (see the debate in Shapiro and Kymlicka 1997). The dialectics of moderating nationalist claims in the context of pluralistic societies might thus lead to a stance which is respectful of cultural differences, but liberal and potentially cosmopolitan in its ultimate goals.

4. Conclusion

The philosophy of nationalism nowadays does not concern itself very much with the aggressive and

dangerous form of invidious nationalism that often occupies center stage in the news and in sociological research. Although this pernicious form can be of significant instrumental value mobilizing oppressed people and giving them a sense of dignity, its moral costs are usually taken by philosophers to outweigh its benefits. Nationalistic-minded philosophers distance themselves from such aggressive nationalism, and mainly seek to construct and defend very moderate versions and these have therefore come to be the main focus of recent philosophical debate.

In presenting the claims that nationalists defend, we have started from more radical ones and have moved towards liberal nationalistic alternatives. In examining the argument for these claims, we have first presented metaphysically demanding communitarian arguments, resting upon deep communitarian assumptions about culture, such as the premise that the ethno-cultural nation is universally the central and most important community for each human individual. This is an interesting and respectable claim, but its plausibility has not yet been established. The moral debate about nationalism has resulted in various weakenings of the cultural arguments, proposed by liberal nationalist, which render the arguments less ambitious but much more plausible. Having abandoned the old nationalistic ideal of a state owned by its ethno-cultural dominant group, liberal nationalists have become receptive to the idea that identification with a multitude of cultures and communities is important for a person's social identity. They have equally become sensitive to trans-national issues, and more willing to embrace a partly cosmopolitan perspective.

Liberal nationalism has also brought to the fore more modest, and less philosophically charged, arguments which are grounded in the concerns of justice and which stress the practical importance of ethno-cultural membership, various rights to redress injustice, democratic rights of political association, and the role that ethno-cultural ties and associations can play in promoting just social arrangements. Liberal culturalists such as Kymlicka have proposed minimal and pluralistic versions of nationalism built around such arguments. In these minimal versions, the project of building classical nation-states is moderated or abandoned, and replaced by a more sensitive form of national identity which can thrive in a multicultural society. This new project, however, might demand a further widening of moral perspectives. Given the experiences of the twentieth century, one can safely assume that culturally-plural states divided into isolated and closed sub-communities glued together only by arrangements of mere *modus vivendi* are inherently unstable. Stability might therefore require that the plural society envisioned by liberal culturalists promote quite intense interaction between cultural groups in order to forestall mistrust, reduce prejudice and create a solid basis for cohabitation. On the other hand, once membership in multiple cultures and communities is admitted as legitimate, social groups will spread beyond the borders of a single state (like many religious or racial ties) as well as within them, thus creating an opening for at least a minimal cosmopolitan perspective. The internal dialectic of the concern for ethno-cultural identity might thus lead to pluralistic and potentially cosmopolitan political arrangements that are rather distant from what was classically understood as nationalism.

A Beginner's Guide to the Literature

This is a short list of books on nationalism that are readable and useful as introductions to the literature. First, the two opposing social science contemporary classics:

- Gellner, E., 1983, *Nations and Nationalism*, Oxford: Blackwell.
- Smith, A. D., 1991, *National Identity*, Harmondsworth: Penguin.

The two best recent anthologies of high-quality philosophical papers on the morality of nationalism, are:

- McKim, R. and McMahan, J. (eds), 1997, *The Morality of Nationalism*, Oxford: Oxford University Press.
- Couture, J., Nielsen, K. and Seymour, M. (eds.), 1998, *Rethinking Nationalism*, Canadian Journal of Philosophy, Supplement Volume 22.

The debate continues in:

- Miscevic, N. (ed), 2000, *Nationalism and Ethnic Conflict. Philosophical Perspectives*, La Salle and Chicago: Open Court.

A good sociological introduction to the gender-inspired criticism of nationalism is:

- Yuval-Davis, N., 1997, *Gender & Nation*, Thousand Oaks-London-New Delhi: Sage Publications.

The best general introduction to the communitarian-individualist debate is still:

- Avineri, Shlomo and de-Shalit, Avner (eds), 1992, *Communitarianism and Individualism*, Oxford: Oxford University Press.

For a non-nationalist defense of culturalist claims see

- Kymlicka, W. (ed), 1995a, *The Rights of Minority Cultures*, Oxford: Oxford University Press.

Two very readable philosophical defenses of very moderate nationalism are:

- Miller, D., 1995, *On Nationality*, Oxford: Oxford University Press.
- Tamir, Y., 1993, *Liberal Nationalism*, Princeton, NJ: Princeton University Press.

An influential critical analysis of group solidarity in general and nationalism in particular, written in the tradition of rational choice theory is:

- Hardin, R., 1985, *One for All, The Logic of Group Conflict*, Princeton, NJ: Princeton University Press

There is a wide offer of interesting sociological and political science work on nationalism, which is beginning to be summarized in

- Motyl, A. (Ed.) 2000, *Encyclopedia of Nationalism, v. I*, New York: Academic Press.

A detailed sociological study of life under nationalist rule is:

- Billig, M., 1995, *Banal Nationalism*, Thousand Oaks-London-New Delhi: Sage Publications.

The most readable short anthology of brief papers for and against cosmopolitanism (and nationalism) by leading authors in the field is:

- Cohen, J. (ed), 1996, Martha Nussbaum and respondents, *For Love of Country: Debating the Limits of Patriotism*, Boston: Beacon Press.

Other Internet Resources

- Nationalism Links (maintained by Peter Rasmussen)
  A good collection of links and bibliographies.

Cosmopolitanism

The word ‘cosmopolitan’, which derives from the Greek word *kosmopolitês* (‘citizen of the world’), has been used to describe a wide variety of important views in moral and socio-political philosophy. The nebulous core shared by all cosmopolitan views is the idea that all human beings, regardless of their political affiliation, do (or at least can) belong to a single community, and that this community should be cultivated. Different versions of cosmopolitanism envision this community in different ways, some focusing on political institutions, others on moral norms or relationships, and still others focusing on shared markets or forms of cultural expression. The philosophical interest in cosmopolitanism lies in its challenge to commonly recognized attachments to fellow-citizens, the local state, parochially shared cultures, and the like.

1. History of Cosmopolitanisms

1.1 Greek and Roman Cosmopolitanism

The political culture that is idealized in the writings of Plato and Aristotle is not cosmopolitan. In this culture, a man identifies himself first and foremost as a citizen of a particular polis or city, and in doing so, he signals which institutions and which body of people hold his allegiance. He would then be counted on for help in defending the city from attacks, sustaining its institutions of justice, and contributing to its common good. In this way, his own pursuit of a good life is inextricably bound to the fate of the city and to the similar pursuit carried out by other inhabitants of the city. By contrast, the good person would not be expected to share with or serve any foreigners who live outside the city. Any cosmopolitan expectations on a good Athenian extended only to concern for those foreigners who happen to reside in Athens.

It would, however, be wrong to assume that Classical Greek thought was uniformly *anti-cosmopolitan*.

Actively excluding foreigners from any ethical consideration or actively targeting foreigners for heinous treatment goes one step beyond focusing one's service and concern on compatriots, and in fact, the targeting of 'barbarians' is historically linked with the rise of panhellenism and not with the more narrow emphasis on the polis. It would be more accurate to call the Classical emphasis on the polis *uncosmopolitan*.

Yet even as Plato and Aristotle were writing, other Greeks were issuing cosmopolitan challenges. Perhaps the most obvious challenges came from the traveling intellectuals who insisted on the contrast between the conventional ties of politics and the natural ties of humanity. Notice, for example, the way Plato has the Sophist Hippias address the motley crew of Athenians and foreigners present at Callias' house in Plato's *Protagoras* (337c7-d3):

> Gentlemen present ... I regard you all as kinsmen, familiars, and fellow-citizens -- by nature and not by convention; for like is by nature akin to like, while convention, which is a tyrant over human beings, forces many things contrary to nature.

Socrates, too, it can be argued, was sensitive to this more cosmopolitan identification with human beings as such. At least as Plato characterizes him, Socrates avoids traditional political engagement as much as he can, in favor of an extraordinary career of examining himself and others, and he insists that these examinations are both genuinely political (*Gorg* 521d6-8) and extended to all, Athenians and foreigners alike (*Apol* 23b4-6). Of course, Socrates chose not to travel widely, but this decision could well have been consistent with cosmopolitan ideals, for he may have thought that his best bet for serving human beings generally lay in staying at home, on account, ironically, of Athens' superior freedom of speech (*Gorg* 461e1-3; cf. *Apol* 37c5-e2 and *Meno* 80b4-7). Whether Socrates was self-consciously cosmopolitan in this way or not, there is no doubt that his ideas accelerated the development of cosmopolitanism and that he was in later antiquity embraced as a citizen of the world. In fact, the first philosopher in the West to give perfectly explicit expression to cosmopolitanism was the Socratically inspired Cynic Diogenes in the fourth century bce. It is said that "when he was asked where he came from, he replied, 'I am a citizen of the world [*kosmopolitês*]'" (Diogenes Laertius VI 63). By identifying himself not as a citizen of Sinope but as a citizen of the world, Diogenes was refusing to agree that he owed special service to Sinope and the Sinopeans. So understood, 'I am a citizen of the cosmos' is a negative claim, and we might wonder if there is any positive content to the Cynic's world-citizenship. The most natural suggestion would be that a world-citizen should serve the world-state, helping to bring it about in order to enable the later work of sustaining its institutions and contributing to its common good. But the historical record does not suggest that Diogenes the Cynic favored the introduction of a world-state. In fact, the historical record does not unambiguously provide Diogenes any positive commitments that we can readily understand as cosmopolitan. The best we can do to find positive cosmopolitanism in Diogenes is to insist that the whole Cynic way of life is supposed to be cosmopolitan: by living in accordance with nature and rejecting what is conventional, the Cynic sets an example of high-minded virtue to all other human beings.

A fuller exploration of positively committed philosophical cosmopolitanism arrives only with the Socratizing and Cynic-influenced Stoics of the third century ce. These Stoics are fond of saying that the cosmos is, as it were, a polis, because the cosmos is put in perfect order by law, which is divine reason.

They also embrace the negative implication of their high standards for order and law: conventional polises do not, strictly speaking, deserve the name. But the Stoics do not believe that living in agreement with the cosmos -- as a citizen of the cosmos -- requires maintaining critical distance from conventional polises. Rather, as the traces of Chrysippus' *On Lives* make clear, the Stoics believe that goodness requires serving other human beings as best one can given the circumstances, that serving all human beings equally well is impossible, and that the best service one can give typically requires political engagement. Of course, the Stoics recognize that political engagement will not be possible for everyone, and that some people will best be able to help other human beings as private teachers of virtue rather than as politicians. But in no case, the Stoics insist, is consideration of political engagement to be limited to one's own polis. The motivating idea is, after all, to help human beings as such, and sometimes the best way to do that is to serve as a teacher or as a political advisor in some foreign place. In this fashion, the Stoics introduce clear, practical content to their metaphor of the cosmopolis: a cosmopolitan considers moving away in order to serve, whereas a non-cosmopolitan does not.

This content admits of a strict and a more moderate interpretation. On the strict view, when one considers whether to emigrate, one recognizes prima facie no special or stronger reason to serve compatriots than to serve a set of human beings abroad. On the moderate view, one does introduce into one's deliberations extra reason to serve compatriots, although one might still, all things considered, make the best choice by emigrating. The evidence does not permit a decisive attribution of one or the other of these interpretations to any of the earliest Stoics. But if we think of a Stoic like Chrysippus as deeply attracted to the Cynics' rejection of what is merely conventional, then we will find it easy to think of Chrysippus as a strict cosmopolitan.

Things are a bit different for at least some of the Stoics at Rome. On the one hand, the cosmopolis becomes less demanding. Whereas Chrysippus limits citizenship in the cosmos to those who in fact live in agreement with the cosmos and its law, Roman Stoics extend citizenship to all human beings by virtue of their rationality. On the other hand, local citizenship becomes more demanding. There is no doubt that the Stoicism of Cicero's *De Officiis* or of Seneca's varied corpus explicitly acknowledges obligations to the *patria*. This is a moderate Stoic cosmopolitanism, and empire made the doctrine very easy for many Romans by identifying the Roman patria with the cosmopolis itself. But neither imperialism nor a literal interpretation of world-citizenship is required for the philosophical point. The maximally committed cosmopolitan looks around to determine whom he can best help and how, knowing full well that he cannot help all people in just the same way, and his decision to help some people far more than others is justified by cosmopolitan lights if it is the best he can do to help human beings as such.

Stoic cosmopolitanism in its various guises was enormously persuasive throughout the Greco-Roman world. In part, this success can be explained by noting how cosmopolitan the world at that time was. Alexander the Great's conquests and the subsequent division of his empire into successor kingdoms sapped local cities of much of their traditional authority and fostered increased contacts between cities, and later, the rise of the Roman Empire united the whole of the Mediterranean under one political power. But it is wrong to say what has frequently been said, that cosmopolitanism arose as a *response* to the fall of the polis or to the rise of the Roman empire. First, the polis' fall has been greatly exaggerated. Under the successor kingdoms and even -- though to a lesser degree -- under Rome, there remained substantial

room for important political engagement locally. Second, and more decisively, the cosmopolitanism that was so persuasive during the so-called Hellenistic Age and under the Roman Empire was in fact rooted in intellectual developments that *predate* Alexander's conquests. Still, there is no doubting that the empires under which Stoicism developed and flourished made many people more receptive to the cosmopolitan ideal and thus contributed greatly to the widespread influence of Stoic cosmopolitanism.

Nowhere was Stoic cosmopolitanism itself more influential than in early Christianity. Early Christians took the later Stoic recognition of two cities as independent sources of obligation and added a twist. For the Stoics, the work of the polis and its citizens and the work of the cosmopolis and its citizens are the same: both aim to improve the lives of the citizens. The Christians respond to a different call: "Render therefore unto Caesar the things which are Caesar's; and unto God the things that are God's" (Matthew 22:21). On this view, the local city may have divine authority (*John* 19:11; cf. *Romans* 13:1,4,7), but the most important work for human goodness is removed from traditional politics, set aside in a sphere in which people of all nations can become "fellow-citizens with the saints" (*Ephesians* 2:20).

This development has two important and long-lasting consequences, which are canonized by Augustine. First, the cosmopolis again becomes a community for certain people only. Augustine makes this point most explicitly by limiting the citizenship in the city of God to those who love God. All others are relegated to the inferior -- though still universal -- earthly city by their love of self. These two cities of the world, which are doomed to coexist intertwined until the Final Judgment, divide the world's inhabitants. Second, the work of politics is severed from the task of building good human lives, lives of righteousness and justice. While Augustine can stress that this allows citizens in the city of God to obey local laws concerning "the necessaries for the maintenance of life," he must also acknowledge that it sets up a potential conflict over the laws of religion and the concerns of righteousness and justice (e.g., *Civitas Dei* XIX 17).

For hundreds of years to come, debates in political philosophy would surround the relation between 'temporal' political authority and the 'universal Church.' But emphasis on the cosmopolitan aspect of the Church waned, despite its ideal of a religious community comprising all humans. In a nutshell, the debate now opposed the secular and the religious, and not the local and the cosmopolitan. Though cosmopolitanism might have featured prominently in medieval political thought, it did not.

1.2 Early Modern and Enlightenment Cosmopolitanism

Cosmopolitanism slowly began to come to the fore again with the renewed study of more ancient texts, but during the humanist era cosmopolitanism still remained the exception. Despite the fact that ancient cosmopolitan sources were well-known and that many humanists emphasized the essential unity of all religions, they did not develop this idea in cosmopolitan terms. A few authors, however, most notably Erasmus of Rotterdam, explicitly drew on ancient cosmopolitanism to advocate the ideal of a world-wide peace. Emphasizing the unity of humankind over its division into different states and peoples, by arguing that humans are destined by Nature to be sociable and live in harmony, Erasmus pleaded for national and

religious tolerance and regarded like-minded people as his compatriots (*Querela Pacis*).

Early modern natural law theory might seem a likely candidate for spawning philosophical cosmopolitanism. Its secularizing tendencies and the widespread individualist view among its defenders that all humans share certain fundamental characteristics would seem to suggest a point of unification for humankind as a whole. However, according to many early modern theorists, what all individuals share is a fundamental striving for self-preservation, and the universality of this striving does not amount to a fundamental bond that unites (or should unite) all humans in a universal community.

Still, there are two factors that do sometimes push modern natural law theory in a cosmopolitan direction: first, the fact that some natural law theorists assume that nature implanted in humans, in addition to the tendency to self-preservation, *also* a fellow-feeling, a form of sociability that unites all humans at a fundamental level into a kind of world community. The appeal to such a shared human bond was very thin, however, and by no means does it necessarily lead to cosmopolitanism. In fact, the very notion of a natural sociability was sometimes used instead to legitimate war against peoples elsewhere in the world who were said to have violated this common bond in an ‘unnatural’ way, or who were easily said to have placed themselves outside of the domain of common human morality by their ‘barbaric’ customs. Second, early modern natural law theory was often connected with social contract theory, and although most social contract theorists worked out their views mostly, if not solely, for the level of the state and not for that of international relations, the very idea behind social contract theory lends itself for application to this second level. Grotius, Pufendorf, and others did draw out these implications and thereby laid the foundation for international law. Grotius envisioned a “great society of states” that is bound by a “law of nations” that holds “between all states” (*De Iure Belli ac Paci*, 1625, Prolegomena par. 17; Pufendorf, *De Iure Naturae et Gentium*, 1672).

The historical context of the philosophical resurgence of cosmopolitanism during the Enlightenment is made up of many factors: The increasing rise of capitalism and world-wide trade and its theoretical reflections; the reality of ever expanding empires whose reach extended across the globe; the voyages around the world and the anthropological so-called ‘discoveries’ facilitated through these; the renewed interest in Hellenistic philosophy; and the emergence of a notion of human rights and a philosophical focus on human reason. Many intellectuals of the time regarded their membership in the transnational ‘republic of letters’ as more significant than their membership in the particular political states they found themselves in, all the more so because their relationship with their government was often strained because of censorship issues. This prepared them to think in terms other than those of states and peoples and adopt a cosmopolitan perspective. Under the influence of the American Revolution, and especially during the first years of the French Revolution, cosmopolitanism received its strongest impulse. The 1789 declaration of ‘human’ rights had grown out of cosmopolitan modes of thinking and reinforced them in turn.

In the eighteenth century, the terms ‘cosmopolitanism’ and ‘world citizenship’ were often used not as labels for determinate philosophical theories, but rather to indicate an attitude of open-mindedness and impartiality. A cosmopolitan was someone who was not subservient to a particular religious or political authority, someone who was not biased by particular loyalties or cultural prejudice. Furthermore, the term

was sometimes used to indicate a person who led an urbane life-style, or who was fond of traveling, cherished a network of international contacts, or felt at home everywhere. In this sense the Encyclopédie mentioned that ‘cosmopolitan’ was often used to signify a “man of no fixed abode, or a man who is nowhere a stranger.” Though philosophical authors such as Montesquieu, Voltaire, Diderot, Addison, Hume, and Jefferson identified themselves as cosmopolitans in one or more of these senses, these usages are not of much philosophical interest.

Especially in the second half of the century, however, the term was increasingly also used to indicate particular philosophical convictions. Some authors revived the Cynic tradition. Fougeret de Montbron in his 1753 autobiographical report, *Le Cosmopolite*, calls himself a cosmopolitan, describes how he travels everywhere without being committed to anywhere, declaring “All the countries are the same to me” and “[I am] changing my places of residence according to my whim” (p. 130).

Despite the fact that there were only few authors who committed themselves to this kind of cosmopolitanism, this was the version that critics of cosmopolitanism took as their target. For example, Rousseau complains that cosmopolitans “boast that they love everyone [*tout le monde*, which also means ‘the whole world’], to have the right to love no one” (Geneva Manuscript version of *The Social Contract*, 158). Johann Georg Schlosser, in the critical poem ‘Der Kosmopolit’ writes, “It is better to be proud of one’s nation than to have none,” obviously assuming that cosmopolitanism implies the latter.

Yet most eighteenth-century defenders of cosmopolitanism did not recognize their own view in these critical descriptions. They understood cosmopolitanism not as a form of ultra-individualism, but rather, drawing on the Stoic tradition, as implying the positive moral ideal of a universal human community, and they did not regard this ideal as inimical to more particular attachments such as patriotism. Some, like the German author Christoph Martin Wieland, stayed quite close to Stoic views. Others developed a cosmopolitan moral theory that was distinctively new. According to Kant, all rational beings are members in a single moral community. They are analogous to citizens in the political (republican) sense in that they share the characteristics of freedom, equality, and independence, and that they give themselves the law. Their common laws, however, are the laws of morality, grounded in reason. Early utilitarian cosmopolitans like Jeremy Bentham, by contrast, defended their cosmopolitanism by pointing to the “common and equal utility of all nations.” Moral cosmopolitanism could be grounded in human reason, or in some other characteristic universally shared among humans (and in some cases other kinds of beings) such as the capacity to experience pleasure or pain, a moral sense, or the aesthetic imagination. Moral cosmopolitans regarded all humans as ‘brothers’ (though with obvious gender bias) -- an analogy with which they aimed to indicate the fundamental equality of rank of all humans, which precluded slavery, colonial exploitation, feudal hierarchy, and tutelage of various sorts.

Some cosmopolitans developed their view into a political theory about international relations. The most radical of eighteenth-century political cosmopolitans was no doubt Anarcharsis Cloots (Jean-Baptiste du Val-de-Grace, baron de Cloots, 1755-1794). Cloots advocated the abolition of all existing states and the establishment of a single world state under which all human individuals would be directly subsumed. His arguments drew first of all on the general structure of social contract theory. If it is in the general interest for everyone to submit to the authority of a state that enforces laws that provide security, then this

argument applies world-wide and justifies the establishment of a world-wide “republic of united individuals,” not a plurality of states that find themselves in the state of nature vis-à-vis each other. Second, he argues that sovereignty should reside with the people, and that the concept of sovereignty itself, because it involves indivisibility, implies that there can be but one sovereign body in the world, namely, the human race as a whole (*La république universelle ou adresse aux tyrannicides,* 1792; *Bases constitutionelles de la république du genre humain,* 1793).

Most other political cosmopolitans did not go as far as Cloots. Immanuel Kant, most famously, advocated a much weaker form of international legal order, namely, that of a ‘league of nations.’ In *Perpetual Peace* (1795) Kant argues that true and world-wide peace is possible only when states are organized internally according to ‘republican’ principles, when they are organized externally in a voluntary league for the sake of keeping peace, and when they respect the human rights not only of their citizens but also of foreigners. He argues that the league of states should not have coercive military powers because that would violate the internal sovereignty of states, constitute a potential danger to individual freedoms already established within those states (if the federal authority were less respectful of human rights than some of the member states) and reduce the chances that states would actually join.

Some critics argued in response that Kant’s position was inconsistent, on the grounds that the only way to fully overcome the state of nature among states was for them to enter into a federative unity of states with coercive powers. They transformed the concept of sovereignty in the process, by conceiving it as layered, and this enabled them to argue that states ought to transfer part of their sovereignty to the federal level, but only that part that concerns their external relations to other states, while retaining the sovereignty of the states concerning their internal affairs (the early Fichte). Romantic authors, on the other hand, felt that the ideal state should not have to involve coercion at all, and hence also that the cosmopolitan ideal should be that of a world-wide republic of ‘fraternal’ non-authoritarian republics (the young Friedrich Schlegel).

Kant also introduced the concept of "cosmopolitan law," suggesting a third sphere of public law -- in addition to constitutional law and international law -- in which both states and individuals have rights, and where individuals have these rights as "citizens of the earth" rather than as citizens of particular states.

In addition to moral and political forms of cosmopolitanism, there emerged an economic form of cosmopolitan theory. The freer trade advocated by eighteenth-century anti-mercantilists like Adam Smith and Dietrich Hermann Hegewisch took greater and greater hold. They sought to diminish the role of politics in the economic realm. Their ideal was a world in which tariffs and other restrictions on foreign trade are abolished, a world in which the market, not the government, takes care of the needs of the people. Against mercantilism, they argue that it is more advantageous for everyone involved if a nation imports those goods which are more expensive to produce domestically, and that the assumption that one’s own state will profit if other states are unable to export their goods is false. They argue that the situation is quite the contrary: the abolition of protectionism would benefit everyone, because other states would gain from their exports, reach a higher standard of living and then become even better trading partners, because they could then import more, too. On their view, after trade will have been liberalized

world-wide, the importance of national governments will diminish dramatically. As national governments currently focus on the national economy and defense, their future role will be at most auxiliary. In the ideal global market, war is in no one's interest. The freer the global market becomes, the more the role of the states will become negligible.

1.3 Cosmopolitanism in the 19th and 20th Centuries

Enlightenment cosmopolitanism has continued to be a source of debate in the subsequent two centuries. First, in the nineteenth century, economic globalization provoked fierce reactions. Marx and Engels tagged cosmopolitanism as an ideological reflection of capitalism. They regard market capitalism as inherently expansive, breaking the bounds of the nation-state system, as evidenced by the fact that production and consumption had become attuned to faraway lands. In their hands, the word 'cosmopolitan' is tied to the effects of capitalist globalization, including especially the bourgeois ideology which legitimatizes 'free' trade in terms of the freedom of individuals and mutual benefit, although this very capitalist order is the cause of the misery of millions, indeed the cause of the very existence of the proletariat. At the same time, however, Marx and Engels also hold that the proletariat in every country shares essential features and has common interests, and the Communist movement aims to convince proletarians everywhere of these common interests. Most famously, the *Communist Manifesto* ends with the call, "Proletarians of all countries, unite!" This, combined with the ideal of the class-less society and the expected withering away of the state after the revolution, implies a form of cosmopolitanism of its own.

Debates about global capitalism and about an international workers' movement have persisted. Frequently economic cosmopolitanism can be found in the advocacy of open markets, in the tradition from Adam Smith to Friedrich von Hayek and Milton Friedman. Communist versions of cosmopolitanism also developed further, although the Leninist-Stalinist tradition kept using 'cosmopolitan' itself as a derogatory term.

The second inheritance from eighteenth century cosmopolitanism is found in the two centuries' worth of attempts to create peace. It has often been noted that there are parallels between Kant's peace proposal in *Perpetual Peace* and the structure of the League of Nations as it existed in the early part of the 20th century as well as the structure of the current United Nations, although it should also be pointed out that essential features of Kant's plan were not implemented, such as the abolition of standing armies. Now, after the end of the cold war, there is again a resurgence of the discussion about the most appropriate world order to promote peace, just as there was after the first and second world wars.

The International Criminal Court should be mentioned here as an innovative form of cosmopolitanism, going much beyond Kant's conception of 'cosmopolitan law.' The ICC itself represents an extension of the long trend, in international law, to do away with the principle of the absolute subjection of individuals to the state and develop the status of individuals under international law. Individuals are now the bearers of certain rights under international law, and they can be held responsible for crimes under international

law in ways that cut through the shield of state sovereignty.

Third, moral philosophers and moralists in the wake of eighteenth-century cosmopolitanisms have insisted that we human beings have a duty to aid fellow humans in need, regardless of their citizenship status. There is a history of international relief efforts (International Red Cross and Red Crescent Societies, famine relief organizations, and the like) in the name of the reduction of human suffering and without regard to the nationality of those affected.

Cosmopolitan duty is not restricted to duties of beneficence and also requires justice and respect, and cosmopolitan morality has often been invoked as a motivation to oppose slavery and apartheid, and to defend the emancipation of women, or, in the utilitarian tradition, to demand better treatment of animals.

Most past cosmopolitan authors did not fully live up to the literal interpretation of their cosmopolitan theories, and one can find misogynist, racist, nationalist, religious, or class-based biases and inconsistencies in their accounts. These shortcomings have often been used as arguments against cosmopolitanism, but they are not as easily used for that purpose as it may seem. Because the universalist potential in the discourse of 'world citizenship' can itself be used as a basis for exposing these shortcomings as problematic, one should say that they stem from too little, rather than too much, cosmopolitanism.

2. Taxonomy of Contemporary Cosmopolitanisms

Even this brief glance backwards reveals a wide variety of views that can be called cosmopolitan. Every cosmopolitan argues for some community among all human beings, regardless of social and political affiliation. For some, what should be shared is simply moral community, which means only that living a good human life requires serving the universal community by helping human beings as such, and/or by promoting the realization of justice and the guarantee of human rights. Others conceptualize the universal community in terms of political institutions to be shared by all, in terms of cultural expressions to be appreciated by all, or in terms of economic markets that should be open to all.

The most common cosmopolitanism -- *moral* cosmopolitanism -- does not always call itself such. But just as ancient cosmopolitanism was fundamentally a 'moral' commitment to helping human beings as such, much contemporary moral philosophy insists on the duty to aid foreigners who are starving or otherwise suffering, and/or on the duty to respect and promote basic human rights and justice. One can here distinguish between strict and moderate forms of cosmopolitanism. The *strict* cosmopolitans in this sphere operate sometimes from utilitarian assumptions (e.g., Singer, Unger), sometimes from Kantian assumptions (e.g., O'Neill), and sometimes from more ancient assumptions (e.g., Nussbaum), but always with the claim that the duty to provide aid neither gets weighed against any extra duty to help locals or compatriots nor increases in strength when locals or compatriots are in question. Among these strict cosmopolitans some will say that it is permissible, at least in some situations, to concentrate one's charitable efforts on one's compatriots, while others deny this -- their position will depend on the details of their moral theory. Other philosophers whom we may call *moderate* cosmopolitans (including, e.g.,

Scheffler) acknowledge the cosmopolitan scope of a duty to provide aid, but insist that we also have special duties to compatriots. Among the moderate cosmopolitans, many further distinctions can be drawn, depending on the reasons that are admitted for recognizing special responsibilities to compatriots and depending on how the special responsibilities are balanced with the cosmopolitan duties to human beings generally. *Anti-cosmopolitanism* in the moral sphere best describes the position of those communitarians (e.g., MacIntyre) who believe either that our obligations to compatriots and more local people crowd out any obligations to benefit human beings as such or that there are no obligations except where there are close, communal relationships.

This debate about moral cosmopolitanism has sometimes led to an inquiry into *political* cosmopolitanism. Again, we can draw useful distinctions among the political cosmopolitans. Some advocate a centralized world state, some favor a federal system with a comprehensive global body of limited power, some would prefer more limited international political institutions that focus on particular concerns (e.g., war crimes, environmental preservation), and some defend a different alternative altogether. Prominent philosophical discussions of international political arrangements have recently clustered around the self-conscious heirs of Kant (e.g., Habermas, Rawls, Beitz, and Pogge) and around advocates of 'cosmopolitan democracy' (e.g., Held, Bohman). Again, there are anti-cosmopolitans, who are skeptical of all international political entanglements.

Perhaps the most common invocations of the label 'cosmopolitan' in recent philosophical literature have been in the disputes over *cultural* cosmopolitanism. Especially with disputes over multiculturalism in educational curricula and with resurgent nationalisms, cultural claims and counter-claims have received much attention. The cosmopolitan position in both of these kinds of disputes rejects exclusive attachments to parochial culture. So on the one hand, the cosmopolitan encourages cultural diversity and appreciates a multicultural mélange, and on the other hand, the cosmopolitan rejects a strong nationalism. In staking out these claims, the cosmopolitan must be wary about very strong 'rights to culture,' respecting the rights of minority cultures while rebuffing the right to unconditional national self-determination. Hence, recent advocates of 'liberal nationalism' (e.g., Margalit and Raz, Tamir) or of the rights of minority cultures (e.g., Kymlicka) generally seem to be anti-cosmopolitan. But the cosmopolitan's wariness towards very strong rights to culture and towards national self-determination need not be grounded in a wholesale skepticism about the importance of parochial cultural attachments. Cosmopolitanism can acknowledge the importance of (at least some kinds of) cultural attachments for the good human life (at least within certain limits), while denying that this implies that a person's cultural identity should be defined by any bounded or homogeneous subset of the cultural resources available in the world (e.g., Waldron).

Economic cosmopolitanism is perhaps less often defended among philosophers and more often among economists (e.g., Hayek, Friedman) and certain politicians, especially in the richer countries of this world. It is the view that one ought to cultivate a single global economic market with free trade and minimal political involvement. It tends to be criticized rather than advanced by philosophical cosmopolitans, as many of them regard it as at least a partial cause of the problem of vast international economic inequality. These debates about the desirability of a fully globalized market have intensified in recent years, as a result of the end of the Cold War and the increasing reach of the market economy.

3. Objections to Cosmopolitanism

One of the most common objections to cosmopolitanism attacks a position that is in fact made of straw. Often it is said that cosmopolitanism is meaningless without the context of a world-state or that cosmopolitanism necessarily involves the commitment to a world state. These claims are historically uninformed, because cosmopolitanism as a concept arose in the first instance as a metaphor for a way of life and not in literal guise. Ever since, there have been cosmopolitans who do not touch on the issue of international political organization, and of those who do, very few defend the ideal of a world state. Furthermore, even those cosmopolitans who do favor a world-state tend to support something more sophisticated that cannot be dismissed out of hand: a thin conception of world government with layered sovereignty.

The more serious and philosophically interesting challenges to cosmopolitanism come in two main forms. The first calls into question the possibility of realizing the cosmopolitan ideal, while the second queries its desirability. We discuss these two challenges to the different forms of cosmopolitanism in turn.

3.1 Political cosmopolitanism

It is often argued that it is impossible to change the current nation-state system and to form a world-state or a global federation of states. This claim is hard to maintain, however, in the face of the existence of the United Nations, the existence of states with more than a billion people of heterogeneous backgrounds, and the experience with the USA and the EU. So in order to be taken seriously, the objection must instead be that it is impossible to form a *good* state or federation of that magnitude, i.e., that it is impossible to realize or even approximate the cosmopolitan ideal in a way that makes it worth pursuing and that does not carry prohibitive risks. Here political cosmopolitans disagree among themselves. On one end of the spectrum we find those who argue in favor of a strong world-state, on the other end we find the defenders of a loose and voluntary federation, or a different system altogether.

The defenders of the loose, voluntary and noncoercive federation warn that a world state easily becomes despotic without there being any competing power left to break the hold of despotism, and the defenders of the world-state reply that a stronger form of federation, or even merger, is the only way to truly exit the state of nature between states. Other authors have argued that the focus among many political cosmopolitans on only these two alternatives overlooks a third, and that a concern for human rights should lead one to focus instead on institutional reform that disperses sovereignty vertically, rather than concentrating it in all-encompassing international institutions. On this view, peace, democracy, prosperity, and the environment would be better served by a system in which the political allegiance and loyalties of persons are widely dispersed over a number of political units of various sizes, without any one unit being dominant and thus occupying the traditional role of the state (Pogge).

Of the objections brought up by non- or anticosmopolitans, two deserve special mention. First, some authors argue that the (partial or whole) surrender of state sovereignty required by the cosmopolitan

scheme is an undue violation of the principle of the autonomy of states or the principle of democratic self-determination of their citizens. Second, so-called ‘realists’ argue that states are in a Hobbesian state of nature as far as the relations among them are concerned, and that it is as inappropriate as it is futile to subject states to normative constraints. To these objections cosmopolitans have various kinds of response, ranging from developing their alternative normative theory (e.g., by arguing that global democracy increases rather than diminishes the democratic control of individual world citizens) to pointing out, as has been done at least since Grotius, that states have good reasons even on Hobbesian grounds to submit to certain forms of international legal arrangements.

3.2 Economic cosmopolitanism

Various arguments have been used to show that economic cosmopolitanism is not a viable option. Marx and later Marxists have argued that capitalism is self-destructive in the long run, because the exploitation, alienation, and poverty that it inflicts on the proletariat will provoke a world-wide revolution that will bring about the end of capitalism. In the twentieth century, when nationalist tendencies proved to be stronger (or in any case more easily mobilized) than international solidarity, and when the position of workers was strengthened to the point of making them unwilling to risk a revolution, this forced the left to reconsider this view.

Critics of the economic cosmopolitan ideal have also started to emphasize another way in which capitalism bears the seeds of its own destruction within itself, namely, insofar as it is said to lead to a global environmental disaster that might spell the end of the human species, or in any event the end of capitalism as we know it. The effects of excessive consumption (in some parts of the world) and the exploitation of nature would make the earth inhospitable to future human generations.

Even if one does not think that these first two problems are so serious as to make economic cosmopolitanism unviable, they can still make it seem *undesirable* in the eyes of those who are concerned with poverty and environmental destruction.

Moreover, there are several other concerns that lead critics to regard economic cosmopolitanism as undesirable. First among these is the lack of effective democratic control by the vast majority of the world’s population, as large multinationals are able to impose demands on states that are in a weak economic position and their populations, demands that they cannot reasonably refuse to meet, although this does not mean that they meet them fully voluntarily. This concerns, for example, labor conditions or the use of raw materials in so-called Third World countries.

Second, economic cosmopolitans are accused of failing to pay attention to a number of probable side-effects of a global free market. In particular, they are criticized for neglecting or downplaying issues such as (a) the presupposition of large-scale migration or re-schooling when jobs disappear in one area (the loss of ties to friends and family, language, culture, etc., and the monetary costs of moving or re-tooling), (b) the lack of a guarantee that there will be a sufficient supply of living-wage jobs for all world citizens (especially given increasing automation), and (c) the problem of the detrimental effects of income

disparities. They are similarly accused of failing to take seriously the fact that there might be circumstances under which it would be profitable for some states to be protectionist or wage war, such as wars about markets or raw materials and energy (e.g., oil).

3.3 Moral cosmopolitanism

Another version of the criticism that cosmopolitanism is impossible targets the psychological assumptions of moral cosmopolitanism. Here it is said that human beings must have stronger attachments toward members of their own state or nation, and that attempts to disperse attachments to fellow-citizens in order to honor a moral community with human beings as such will cripple our sensibilities. If this is a *viability* claim and not simply a *desirability* claim, then it must be supposed that moral cosmopolitanism would literally leave large numbers of people unable to function. So it is claimed that people need a particular sense of national identity in order to be agents, and that a particular sense of national identity requires attachment to particular others perceived to have a similar identity. This argument seems plausible if it is assumed that cosmopolitanism requires the same attitudes towards all other human beings, but moderate cosmopolitanism does not make that assumption. Rather, the moderate cosmopolitan has to insist only that there is some favorable, motivating attitude toward all human beings as such; this leaves room for some special attitudes towards fellow-citizens. Of course, the strict moral cosmopolitan will go further and will deny that fellow-citizens deserve any special attitudes, and it might be thought that this denial is what flouts the limits of human psychology. But this does not seem to be true as an empirical generalization. The cosmopolitan does not need to deny that some people do happen to have the need for national allegiance, so long as it is true that not all people do; and insofar as some people do, the strict cosmopolitan will say that perhaps it does not need to be that way and that cosmopolitan education might lead to a different result. The historical record gives even the strict cosmopolitan some cause for cheer, as human psychology and the forms of political organization have proven to be quite plastic.

In fact, some cosmopolitans have adopted a developmental psychology according to which patriotism is a step on the way to cosmopolitanism: as human individuals mature they develop ever wider loyalties and allegiances, starting with attachments to their caregivers and ending with allegiance to humanity at large. These different attachments are not necessarily in competition with each other. Just as little as loyalty to one's family is generally seen as a problematic feature of citizens, so the argument goes, loyalty to one's state is not a necessarily problematic feature in the eyes of cosmopolitans. Thus, cosmopolitanism is regarded as an extension of a developmental process that also includes the development of patriotism. This claim is just as much in need of empirical support, however, as the opposite claim discussed in the previous paragraph.

Often, though, the critic's arguments about psychological possibility are actually run together with *desirability* claims. The critic says that the elimination of a special motivating attachment to fellow-citizens is not possible, but the critic means that the elimination of special motivating attachments to fellow-citizens will make a certain desirable form of political life impossible. To respond to this sort of argument, the cosmopolitan has two routes open. First, she can deny the claim itself. Perhaps the viability of politics as usual depends not upon certain beliefs that fellow-citizens deserve more of one's service,

but upon commitments to the polity itself. If strictly cosmopolitan patriotism is a possibility, it lives in a commitment to a universal set of principles embodied in a particular political constitution and a particular set of political institutions. If such commitment is enough for desirable politics, then the anti-cosmopolitan is disarmed. But second, the cosmopolitan can of course also deny the value of the form of political life that is posited as desirable. At this point, moral commitments run over into a discussion of political theory.

Occasionally it is said that cosmopolitans are treasonous or at least unreliable citizens. But many recognizably cosmopolitan theses (that is, the moderate ones) are consistent with loyalty to fellow-citizens, and even the strictest cosmopolitan can justify some forms of service to fellow-citizens when they are an optimal way to do good for human beings (who happen to be fellow-citizens, and not *because* they are fellow-citizens).

This last criticism can be developed further, however, and tailored specifically to target the strict cosmopolitan. If the strict cosmopolitan can justify only some forms of service to fellow-citizens, under some conditions, it might be said that she is blind to other morally required forms or conditions of service to fellow-citizens. At this point, the critic offers reasons why a person has special obligations to compatriots, which are missed by the strict cosmopolitan. Many critics who introduce these reasons are themselves moderate cosmopolitans, wishing to demonstrate that there are special obligations to fellow-citizens in addition to general duties to the community of all human beings. But if these reasons are demanding enough, then there may be no room left for any community with all human beings, and so these objections to strict cosmopolitanism can also provide some impetus toward an anti-cosmopolitan stance. Because there are several such reasons that are frequently proposed, there are, in effect, several objections to the strictly cosmopolitan position, and they should be considered one-by-one.

The first narrow objection to strict cosmopolitanism is that it neglects the obligations of reciprocity. According to this argument, we have obligations to give benefits in return for benefits received, and we receive benefits from our fellow-citizens. The best strictly cosmopolitan response to this argument will insist on a distinction between the state and fellow-citizens and will question exactly who provides which benefits and what is owed in return. On grounds of reciprocity the state may be owed certain things -- cooperative obedience -- and these things may in fact generally benefit fellow-citizens. But the state is not owed these things *because* one owes the fellow-citizens benefits. One does not appropriately signal gratitude for benefits received from the state by, say, giving more to local charities than to charities abroad because charity like this does not address the full agent responsible for the benefits one has received, and does not even seem to be the sort of thing that is commensurate with the benefits received. In assessing this exchange of arguments, there are some significantly difficult questions to answer concerning exactly how the receipt of benefits obliges one to make a return and concerning how the benefits one receives from one’s state affect the acceptability of emigration.

A second objection to strict moral cosmopolitanism gives contractarian grounds for our obligations to fellow-citizens. Because actual agreements to prioritize fellow-citizens as beneficiaries are difficult to find, the contractarians generally rely upon an implicit agreement that expresses the interests or values of the fellow-citizens themselves. So the contractarian argument turns on identifying interests or values that

obligate fellow-citizens to benefit each other. Perhaps, then, it will be argued that citizens have deep interests in what a successful civil society and state can offer them, and that these interests commit the citizens to an implicit agreement to benefit fellow-citizens. The strict cosmopolitan will reply to such an argument with skepticism about what is required for the civil society. Why is more than cooperative obedience required by our interests in what a successful state and civil society can provide? Surely some citizens have to dedicate themselves to working on behalf of this particular society, but why can they not do so on the grounds that this is the best way to benefit human beings as such? Perhaps an intermediate position here is the (Kantian) view that it is morally necessary to establish just democratic states and that just democratic states need some special commitment on the part of their citizens in order to function as democracies, a special commitment that goes beyond mere cooperative obedience but that can still be defended in universalist cosmopolitan terms. The acceptability of this type of view, however, will depend on whether one finds convincing the underlying Kantian political theory.

The final argument for recognizing obligations to benefit fellow-citizens appeals to what David Miller has called ‘relational facts.’ Here the general thought is that certain relationships are constituted by reciprocal obligations: one cannot be a friend or a brother without having certain friendship-obligations or sibling-obligations, respectively. If fellow-citizenship is like these other relations, then we would seem to have special obligations to fellow-citizens. But this argument, which can be found in Cicero’s *De Officiis*, depends upon our intuitions that fellow-citizenship is like friendship or brotherhood and that friendship and brotherhood do come with special obligations, and both intuitions require more argument. Frequently, these arguments appeal to alleged facts about human nature or about human psychology, but these appeals generally raise still further questions.

In sum, a range of interesting and difficult philosophical issues is raised by the disputes between cosmopolitans of various stripes and their critics. As the world becomes a smaller place through increased social, political, and economic contacts, these disputes and the issues they raise will only become more pressing.

War

One apt definition of war is this: war is an actual, intentional and widespread armed conflict between political communities. Thus, a fisticuffs between individual persons does not count as a war, nor does a gang fight, nor does a feud on the order of the Hatfields versus the McCoys. War is a phenomenon which occurs only between political communities, defined as those entities which either are states or intend to become states (in order to allow for civil war). Similarly, the mere threat of war and the presence of mutual disdain between these communities do not suffice as indicators of war. The conflict of arms must be actual and not merely latent. Further, the actual armed conflict must be both intentional and widespread: isolated clashes between rogue officers, or border patrols, do not count as actions of war. The onset of war requires a conscious commitment, and a significant mobilization, on the part of the belligerent communities in question.

Perhaps it would be appropriate here to cite the legendary Carl von Clausewitz. Clausewitz famously suggested that "war is the continuation of policy by other means." As a description, this conception is both powerful and plausible. It fits in nicely with his own general definition of war as "an act of violence intended to compel our opponent to fulfil our will." War, he says, is like a duel, but on "an extensive scale." As Michael Gelven has written recently, in an elegant monograph on how we ought to conceive of the essence of war, war is intrinsically vast, communal (or political) and violent. It is a widespread and deliberate armed conflict between political communities. It is the entity or phenomenon falling under such a description which is the primary focus of this entry.

The Ethics of War and Peace

One of the most enduring, and difficult, philosophical questions with regard to war focuses on the ethics of getting involved with it in the first place. It is most helpful, in ordering one's thoughts about this issue, to realize that there are three traditions of thought which dominate the philosophical treatment of this topic. This is not necessarily to imply that these three traditions exhaust all possible options for thinking about the ethics of war and peace, merely to note that they are hegemonic and importantly different from each other. But very few theories on the ethics of war succeed in resisting ultimate classification into one of them. The three traditions are: JUST WAR THEORY; REALISM; and PACIFISM.

Before spending some time discussing the core aspects of each tradition, let's declare, right from the start, the core conceptual differences between "the big three" perspectives. The core, and controversial, proposition of just war theory is that, sometimes, states can have moral justification for resorting to armed force in the international system. War is sometimes, but of course not all the time, morally right. The idea here is not that the war in question is merely politically shrewd, or prudent, or bold and daring, but fully moral, just. It is an ethically appropriate use of mass political violence. Realism, by contrast, sports a profound skepticism about the application of moral concepts, such as justice, to the key problems of foreign policy. Power and national security, realists claim, motivate states during wartime and thus moral appeals are strictly wishful thinking. Talk of the morality of warfare is pure bunk: ethics has got nothing to do with the rough-and-tumble world of global politics, where only the strong and cunning survive. Pacifism does not share realism's moral skepticism. For the pacifist, moral concepts can indeed be applied fruitfully to international affairs. It does make sense to ask whether a war is just. But the result of such normative application, in the case of war, is always that war should not be resorted to. Where just war theory is sometimes permissive with regard to war, pacifism is always prohibitive. For the pacifist, war is always wrong. Now let's turn to each of these three traditions.

Just War Theory

Just war theory is probably the most influential perspective on the ethics of war and peace. The just war tradition has enjoyed a long and distinguished pedigree, including such notables as Augustine, Aquinas, Grotius, Suarez, Vattel and Vitoria. Hugo Grotius probably deserves credit for being the most comprehensive and formidable member of the tradition; and James T. Johnson is the authoritative historian of this tradition. Many of the rules developed by the just war tradition have since been codified into contemporary international laws governing armed conflict, such as The Hague and Geneva Conventions. The tradition has thus been doubly influential, dominating both moral and legal discourse surrounding war. It sets the tone, and the parameters, for the great debate.

Just war theory can be meaningfully divided into three parts, which in the literature are referred to, for the sake of convenience, in Latin. These parts are: 1) *jus ad bellum*, which concerns the justice of resorting to war in the first place; 2) *jus in bello*, which concerns the justice of conduct within war, after it has begun; and 3) *jus post bellum*, which concerns the justice of peace agreements and the termination phase of war.

Jus ad bellum

The rules of *jus ad bellum* are addressed, first and foremost, to heads of state. Since political leaders are the ones who inaugurate wars, setting their armed forces in motion, they are to be held accountable to *jus ad bellum* principles. If they fail in that responsibility, then they commit war crimes. In the language of the Nuremberg prosecutors, aggressive leaders who launch unjust wars commit "crimes against peace." What constitutes a just or unjust resort to armed force is disclosed to us by the rules of *jus ad bellum*. Just war theory contends that, for any resort to war to be justified, a political community, or state, must fulfil each and every one of the following six requirements:

1. Just cause. A state may launch a war only for the right reason. The just causes most frequently mentioned include: self-defence from external attack; the protection of innocents; and punishment for wrongdoing. Vitoria suggested that all of the proffered just causes be subsumed under the one category of "a wrong received." Walzer, and most modern just war theorists, speak of the one just cause for resorting to war being the resistance of aggression. Aggression, simply put, is unjustified and harmful violence.

The key principle underlying just cause, and just war theory more broadly, is the vindication of fundamental rights and the protection of those who have such rights from serious, standard threats to them, such as aggression. Self-defence, and other-defence, from rights violating aggression are thus prime just causes for resorting to war. These rights are traditionally understood as the rights of states to political sovereignty and territorial integrity: states have the right to make their own political decisions for their own people, within their own borders. Only if these rights are violated - for instance, through an armed invasion across the border - is a country justified in resorting to a war of self-defence in response. Other countries may join the war on the victim's side, since the aggressor forfeits its state rights when it violates the victim's.

But what grounds the importance of these state rights? States have state rights, to things like sovereignty and integrity, only because their individual citizens have human rights. People create, and adhere to, state structures in order to secure the objects of their human rights. Human rights are elemental entitlements we all have to basic human dignity and to the objects of vital human need. The human rights most broadly endorsed are those to life, liberty and subsistence, for instance as enshrined in the United Nation's Universal Declaration and subsequent International Covenants.

Following John Rawls, we might establish criteria of minimal justice (MJ) which a state must fulfil if it is to be entitled to state rights: MJ 1) it is able to rule its people in accord with law and order; MJ 2) it provides its people with secure access to the objects of their human rights; and MJ 3) it adheres to basic norms of international justice, notably respect for the rights of persons and other minimally just states. Thus, a state which commits aggression against the people of another country violates principle MJ 3, and thus fails to be minimally just. A minimally just state forfeits its right not to be dealt with harshly, as a matter of appropriate punishment and rectification.

2. Right intention. A state must intend to fight the war only for the sake of a just cause. Having the right reason for launching a war is not enough: the actual motivation behind the resort to war must also be morally appropriate. Ulterior motives, such as a power or land grab, or irrational motives, such as

revenge or ethnic hatred, are ruled out. The only right intention allowed is to see the just cause for resorting to war secured and consolidated. If another intentions crowd in, moral corruption sets in.

3. Proper authority and public declaration. A state may go to war only if the decision has been made by the appropriate authorities, according to the proper process, and made public, notably to its own citizens and to the enemy state(s).

4. Last Resort. A state may resort to war only if it has exhausted all plausible, peaceful alternatives to resolving the conflict in question, in particular diplomatic negotiation. One wants to make sure something as momentous and serious as war is declared only when it seems the only reasonable alternative to effectively punish aggression.

5. Probability of Success. A state may not resort to war if it can foresee that doing so will have no measurable impact on the situation. The aim here is to block mass violence which is going to be futile.

6. (Macro-) Proportionality. A state must, prior to initiating a war, weigh the universal goods expected to result from it, such as securing the just cause, against the universal evils expected to result, notably casualties. Only if the benefits are proportional to, or "worth", the costs may the war action proceed.

Just war theory insists all six criteria must each be fulfilled for a particular declaration of war to be justified: it's all or no justification, so to speak. It is important to note that the first three of these six rules are what we might call deontological requirements, otherwise known as duty-based requirements or first-principle requirements. For a war to be just, some core duty must be violated: in this case, the duty not to commit aggression. A war in punishment of this violated duty must itself respect further duties: it must be appropriately motivated, and must be publicly declared by (only) the proper authority for doing so. The next three requirements are consequentialist: given that these first principle requirements have been met, we must also consider the expected consequences of launching a war which seems justified according to first principles. Thus, just war theory attempts to provide a common sensical combination of both deontology and consequentialism as applied to the issue of war.

Jus in bello

Jus in bello refers to justice in war, to right conduct in the midst of battle. Responsibility for state adherence to *jus in bello* norms falls primarily on the shoulders of those military commanders, officers and soldiers who formulate and execute the war policy of a particular state. They are to be held responsible for any breach of the principles which follow below. Such accountability may involve being put on trial for war crimes.

Just war theorists insist that *jus in bello* is a category separate from *jus ad bellum*. For even if a state has resorted to war justly, it may be prosecuting that war in an unjustified manner. It may be deploying decrepit means in pursuit of its otherwise justified end. Just war theory insists on a fundamental moral consistency between means and ends with regard to wartime behaviour: justified ends may only be

pursued through justified means.

Concern with consistency, however, is not the only, or even the main, reason behind the endorsement of separate rules regulating wartime conduct. Such rules are also required to limit warfare, to prevent it from spilling over into an ever-escalating, and increasingly destructive, experiment in total warfare. If just wars are limited wars, designed to secure their just causes with only proportionate force, the need for rules on wartime restraint is clear. Even though modern warfare has displayed a disturbing tendency towards totality - particularly during the two World Wars - it does not follow that the death of old-time military chivalry marks the end of moral judgment. We still hold soldiers to certain standards of conduct.

There are three widely recognized rules of *jus in bello*.

1. Discrimination. Soldiers are only entitled to target those who are, in Walzer's words, "engaged in harm." Thus, when they take aim, soldiers must discriminate between the civilian population, which is morally immune from direct and intentional attack, and those legitimate military, political and industrial targets involved in rights-violating harm. While some collateral civilian casualties are excusable, it is wrong to take deliberate aim at civilian targets. An example would be saturation bombing of residential areas.

2. (Micro-) Proportionality. Soldiers may only use force proportional to the end they seek. Weapons of mass destruction, for example, are usually seen as being out of proportion to legitimate military ends.

3. No Means *Mala in Se*. Soldiers may not use weapons or methods which are "evil in themselves." These include: mass rape campaigns; genocide or ethnic cleansing; torturing captured enemy soldiers; and using weapons whose effects cannot be controlled, like chemical or biological agents.

Jus post bellum

Jus post bellum refers to justice during the third and final stage of war: that of war termination. It seeks to regulate the ending of wars, and ease the transition from war back to peace. It is one of the most recent, and topical, issues in just war theory. See Orend's works in the bibliography below for more. Orend proposes the following rules for *jus post bellum*:

1. Just cause for termination. A state has just cause to seek termination of the just war in question if there has been a reasonable vindication of those rights whose violation grounded the resort to war in the first place. Not only have most, if not all, unjust gains from aggression been eliminated and the objects of the victim's rights been reasonably restored, but the aggressor is now willing to accept terms of surrender which include not only the cessation of hostilities, a formal apology and its renouncing the gains of its aggression but also its submission to reasonable principles of punishment, including compensation, war crimes trials, and perhaps rehabilitation.

2. Right intention. A state must intend to carry out the process of war termination only in terms of those

principles contained in the other *jus post bellum* rules. Revenge is strictly ruled out as an animating force. Moreover, the just state in question must commit itself to symmetry and equal application with regard to the investigation and prosecution of any war crimes its own armed forces may have committed on the battlefield.

3. Public declaration and legitimate authority. The terms of the peace must be publicly proclaimed by a legitimate authority, which is to say the national government of the state victimized by the initial aggression, or perhaps an authorized international body.

4. Discrimination. In setting the terms of the peace, the just and victorious state is to differentiate between the political and military leaders, the soldiers and the civilian population within the aggressor. Undue and unfair hardship is not to be brought upon the civilian population in particular: punitive measures are to be focused upon those elites most responsible for the aggression.

5. Proportionality. Any terms of peace must be proportional to the end of reasonable rights vindication. Absolutist crusades against, and/or draconian punishments for, aggression are especially to be avoided. The people of the defeated aggressor never forfeit their human rights, and so are entitled not to be "blotted out" from the community of nations. There is thus no such thing as a morally-mandated unconditional surrender.

Any serious defection from these principles of *jus post bellum*, on the part either of the victim or the aggressor, is a violation of the rules of just war and so should be punished. At the very least, such violation of *jus post bellum* mandates a new round of good-faith diplomatic negotiations - perhaps even binding international arbitration - between the relevant parties to the dispute. At the very most, such violation gives the aggrieved party a just cause - but no more than a just cause - for resuming hostilities. Full recourse to the resumption of hostilities may be made only if all the other criteria of *jus ad bellum* are satisfied in addition to just cause.

Just war theory thus offers rules to guide decision-makers on the appropriateness of their conduct during the resort to war, conduct during war and the termination phase of the conflict. Its over-all aim is to try and ensure that wars are begun only for a very narrow set of truly defensible reasons, that when wars break out they are fought in a responsibly controlled and targeted manner, and that the parties to the dispute bring their war to an end in a speedy and responsible fashion that respects the requirements of justice.

Realism

Realism is most influential amongst political scientists, as well as scholars and practitioners of international relations. While realism is a complex and often sophisticated doctrine, its core propositions express a strong suspicion about applying moral concepts, like justice, to the conduct of international affairs. Realists believe that moral concepts should be employed neither as descriptions of, nor as prescriptions for, state behaviour on the international plane. Realists emphasize power and security

issues, the need for a state to maximize its expected self-interest and, above all, their view of the international arena as a kind of anarchy, in which the will to power enjoys primacy.

Referring specifically to war, realists believe that it is an intractable part of an anarchical world system; that it ought to be resorted to only if it makes sense in terms of national self-interest; and that, once war has begun, a state ought to do whatever it can to win. In other words, "all's fair in love and war." During the grim circumstances of war, "anything goes." So if adhering to the rules of just war theory, or international law, hinders a state during wartime, it should disregard them and stick steadfastly to its fundamental interests in power and security. Prominent classical realists often mentioned include Thucydides, Machiavelli and Hobbes. Modern realists include Hans Morgenthau, George Kennan, Reinhold Niebuhr and Henry Kissinger, as well as so-called neo-realists, such as Kenneth Waltz.

It is important to distinguish between descriptive and prescriptive realism. Descriptive realism is the claim that states, as a matter of fact, either do not (for reasons of motivation) or cannot (for reasons of competitive struggle) behave morally, and thus moral discourse surrounding interstate conflict is empty, the product of a category mistake. States are simply not animated in terms of morality and justice: it's all about power, security and national interest for them. States are not like "big persons": they are creations of an utterly different kind, and we cannot expect them to live by the same rules and principles we require of individual persons. States inhabit a violent international arena, and they've got to be able to get in that game and win, if they are to serve and protect their citizens in an effective way over time. Morality is simply not on the radar screen for creations such as states, given their defensive function and the brutal environment in which they subsist.

Walzer offers arguments against this kind of realism, contending that states are in fact responsive to moral concerns, even when they fail to live up to them. States, because they are the creation of individual persons, want to act morally and justly. Walzer goes so far as to say that any state which was motivated by nothing more than the struggle to survive and win power could not over time sustain the support from its own population, which demands a deeper sense of community and justice. He also argues that all the pretence regarding "the necessity" of state conduct in terms of pursuing power is exaggerated and rhetorical, ignoring the clear reality of foreign policy choice enjoyed by states in the global arena. States are not frequently forced into some kind of dramatic, do-or-die struggle: the choice to go to war is a deliberate one, freely entered into and often hotly debated and agonized over before the decision is made. And this is leaving unspoken the argument regarding the defiant, Machiavellian amorality behind certain kinds of realism, and the moral calibre of the actions it might recommend on this basis. For example, if it's all about power and winning in the competitive struggle, does that make it alright to unleash weapons of mass destruction? Or to launch a mass rape campaign? Just war theory suggests not, and just war theorists like Walzer want to claim that the rest of us agree.

Prescriptive realism, though, need not be rooted in any form of descriptive realism. Prescriptive realism is the claim that a state ought (prudential "ought") to behave amorally in the international arena. A state should, for prudence's sake, adhere to an amoral policy of smart self-regard in international affairs. A smart state will leave its morality at home when considering what to do on the international stage. It's important to note that a prescriptive realist might, in the end, actually endorse rules for the regulation of

warfare, much like those offered by just war theory. These rules include: "Wars should only be fought in response to aggression"; and "During war, non-combatants should not be directly targeted with lethal violence." Of course, the reason why a prescriptive realist might endorse such rules would be very different from the reasons offered by the just war theorist: the latter would talk about abiding moral values whereas the former would refer to useful rules which help establish expectations of behaviour, solve coordination problems and to which prudent bargainers would consent. Just war rules, the prescriptive realist might claim, do not have independent moral purchase on the attention of states. These rules are what Douglas Lackey calls "salient equilibria", stable conventions limiting war's destructiveness which all prudent states can agree on, assuming general compliance. There might even be some room for overlap between this kind of realism and just war theory.

Pacifism

It seems best to rely on Jenny Teichman's definition of pacifism as "anti-war-ism." Literally and straightforwardly, a pacifist rejects war in favour of peace. It is not violence in all its forms that the most challenging kind of pacifist objects to; rather, it is the specific kind and degree of violence that war involves which the pacifist objects to. A pacifist objects to killing (not just violence) in general and, in particular, she objects to the mass killing, for political reasons, which is part and parcel of the wartime experience. So, a pacifist rejects war; she believes that there are no moral grounds which can justify resorting to war. War, for the pacifist, is always wrong.

Mention should straight away be made of a very popular just war criticism of pacifism which will not be used here. This criticism is that pacifism amounts to an indefensible "clean hands policy." The pacifist, it is said, refuses to take the brutal measures necessary for the defense of himself and his country, for the sake of maintaining his own inner moral purity. It is contended that the pacifist is thus a kind of free-rider, gathering all the benefits of citizenship while not sharing all its burdens. Another inference drawn is that the pacifist himself constitutes a kind of internal threat to the over-all security of his state.

This "clean hands" argument is easily, and frequently, over-stated. It is important to note that, to the extent to which any moral stance will commend a certain set of actions or intentions deemed morally worthy, and condemn others as being reprehensible, the "clean hands" criticism can be so malleable as to apply to nearly any substantive doctrine. Every moral and political theory stipulates that one ought to do what it deems good or just and to avoid what it deems bad or unjust. So this popular just war criticism of pacifism is not strong. The very idea of a selfish pacifist simply does not ring true: many pacifists have, historically, paid a very high price for their pacifism during wartime (through severe ostracism and even jail time) and their pacifism seems less rooted in regard for inner moral purity than it is in regard for constructing a less violent and more humane world order. So, this argument against pacifism fails; but what of others?

Walzer, the just war theorist, contends that pacifism's idealism is excessively optimistic. In other words, pacifism lacks realism. More precisely, the nonviolent world imagined by the pacifist is not actually attainable, at least for the foreseeable future. Since "ought implies can", the set of "oughts" we are

committed to must express a moral outlook on war less utopian in nature. While we are committed to morality in wartime, we are forced to concede that, sometimes in the real world, resorting to war can be morally justified.

Another objection to pacifism is that, by failing to resist international aggression with effective means, it ends up rewarding aggression and failing to protect people who need it. Pacifists reply to this argument by contending that we do not need to resort to war in order to protect people and punish aggression effectively. In the event of an armed invasion by an aggressor state, an organized and committed campaign of non-violent civil disobedience - perhaps combined with international diplomatic and economic sanctions - would be just as effective as war in expelling the aggressor, with much less destruction of lives and property. After all, the pacifist might say, no invader could possibly maintain its grip on the conquered nation in light of such systematic isolation, non-cooperation and non-violent resistance. How could it work the factories, harvest the fields, or run the stores, when everyone would be striking? How could it maintain the will to keep the country in the face of crippling economic sanctions and diplomatic censure from the international community? And so on.

Though one cannot exactly disprove this pacifist proposition - since it is a counter-factual thesis - there are powerful reasons to agree with John Rawls that such is "an unworldly view" to hold. For, as Walzer points out, the effectiveness of this campaign of civil disobedience relies on the scruples of the invading aggressor. But what if the aggressor is brutal, ruthless? What if, faced with civil disobedience, the invader "cleanses" the area of the native population, and then imports its own people from back home? What if, faced with economic sanctions and diplomatic censure from a neighbouring country, the invader decides to invade it, too? We have some indication from history, particularly that of Nazi Germany, that such pitiless tactics are effective at breaking the will of people to resist. The defence of our lives and rights may well, against such invaders, require the use of political violence. Under such conditions, Walzer says, adherence to pacifism would amount to "a disguised form of surrender."

Pacifists respond to this accusation of "unworldliness" by citing what they believe are real world examples of effective non-violent resistance to aggression. Examples mentioned include Mahatma Ghandi's campaign to drive the British Imperial regime out of India in the late 1940s and Martin Luther King Jr.'s civil rights crusade in the 1960s on behalf of African-Americans. Walzer replies curtly that there is no evidence that non-violent resistance has ever, of itself, succeeded. This may be rash on his part, though it is clear that Britain's own exhaustion after WWII, for example, had much to do with the evaporation of its Empire. Walzer's main counter-argument against these pacifist counter-examples is that they only underline his main point: that effective non-violent resistance depends upon the scruples of those it is aimed against. It was only because the British and the Americans had some scruples, and were moved by the determined idealism of the non-violent protesters, that they acquiesced to their demands. But aggressors will not always be so moved. A tyrant like Hitler, for example, might interpret non-violent resistance as weakness, deserving contemptuous crushing. "Non-violent defense", Walzer suggests, "is no defense at all against tyrants or conquerors ready to adopt such measures."

As sensible as Walzer's remarks might seem, they remain quite narrow, by no means constituting an all-things-considered refutation of pacifism. Generally, there are two kinds of modern secular pacifism to

consider: 1) a more consequentialist form of pacifism (or CP), which maintains that the benefits accruing from war can never outweigh the costs of fighting it; and 2) a more deontological form of pacifism (or DP), which contends that the very activity of war is intrinsically wrong, since it violates foremost duties of justice, such as not killing human beings. Most common amongst contemporary secular pacifists, such as Robert Holmes, is a doctrine which attempts to combine both CP and DP. (I might add, parenthetically, that no discussion will be made here as to religious forms of pacifism. While they have been very influential historically, especially their Christian variants, as theoretical propositions I believe they rest on core premises which are too contentious and exclusionary. But the Christian pacifist literature is a very rich source of information for those interested.)

What arguments might a just war theorist employ to overcome CP and DP? A just war theorist might, for starters, focus on the relationship in CP between consequentialism and the denial of killing. Pacifism in either form places overriding value on respecting human life, notably through its injunction against killing. But this value seems to rest uneasily with consequentialism, for there is nothing inherent to consequentialism which bans killing as such. There is no absolute rule, or side-constraint, that one ought never to kill another person, or that nations ought never to deploy lethal armed force in war. With consequentialism, it's always a matter of considering the latest costs and benefits, of choosing the best option amongst feasible alternatives. Consequentialism therefore leaves conceptual space open to the claim that under these conditions, at this time and place, and given these alternatives, killing and/or war appears permissible. After all, what if killing x people (say, soldiers in an aggressive army) appears the best option if we are to save the lives of x + n people (say, fellow citizens who would perish under the brutal heel of an unchecked aggressor)? It is at least conceivable that a quick and decisive resort to war could prevent even greater killing and devastation in the future. So it seems problematic for the consequentialist pacifist, whose principles exhibit a profound abhorrence for killing people, to be willing in such a scenario to allow an even greater number of people to be killed by acquiescing to the violence of others less scrupulous. These are two telling points: CP does not, of itself, ground the categorical rejection of killing and war which is the essence of pacifism; and CP is open to counter-examples which question whether consequentialism would reject killing and war at all under certain conditions. Consequentialism might even, in a particular case, go so far as to recommend war under certain conditions.

Casting doubt on DP is a complicated procedure. Only a sketch of plausible just war theory arguments can here be offered. The first question to ask is: which foremost duty does DP understand being violated by warfare? If the DP response is the duty not to kill another human being, then contention can be made that this is by no means uncontroversial. Consider the most obvious counter-example: aggressor A attacks B for no defensible reason, posing a serious threat to B's life. Some would suggest, in good faith, that B is not duty-bound not to kill A if such seems necessary to stop A's aggression. Indeed, they would argue that B may kill A in legitimate self-defence. The DP pacifist, however, might reply that extending B moral permission to kill A, even in self-defence, violates the human rights of A. He might contend that just war theory merely compounds the wrongness of the situation by paradoxically permitting lethal force to stop lethal force.

One just war theory rejoinder to this DP contention is this: B does no wrong whatsoever - violates no

human rights - by responding to A's aggression with lethal force if required. Why does B do nothing wrong? First, it is A who is responsible for forcing B to choose between her own life and rights and those of A. We can hardly blame B for choosing her own. For if she does not choose her own, she loses an enormous amount, perhaps everything. And it is patently unreasonable to expect creatures like us to suffer catastrophic loss by default. Consider also the issue of fairness: if B is not allowed to use lethal force, if necessary, against A in the event of A's aggression, then B loses everything while A loses nothing. Indeed, A gains whatever object he desired in violating or killing B. Such would seem an unfair reward of awful behaviour. Finally, B's having rights at all provides her with an implicit entitlement to use those means necessary to secure her rights, including the use of force in the face of a serious physical threat. These powerful considerations of responsibility, reasonableness, fairness and implicit entitlement come together in support of the just war claims that: B may respond with needed lethal force to A's initial aggression; B does no wrong in doing so; it would be wrong to prohibit B's doing so; and that A bears all of the blame for the situation.

DP pacifists are not, at this point, out of options. Holmes, for example, suggests that the foremost duty of justice violated by war is not the duty not to kill aggressors, but rather the duty not to kill innocent, non-aggressive human beings. To be innocent here means to have done nothing which would justify being harmed or killed; in particular, it means not constituting a serious threat to the lives and rights of other people. It is this sense of innocence that just war theory invokes when it claims that civilians should not be directly attacked during wartime. Even if civilians support the war effort politically, or even in terms of their personal attitudes towards the war, they clearly do not pose serious threats to others. Only armed forces, and the political-industrial-technological complexes which guide them, constitute serious threats against which threatened communities may respond in kind. Civilian populations, just war theory surmises, are morally off-limits as targets. Holmes contends that this just war rule of non-combatant immunity can never be satisfied. For all possible wars in this world - given the nature of military technology and tactics, the heat of battle, and the limits of human knowledge and self-discipline - involve the killing of innocents, thus defined. We know this to be true from history and have no good reason for expecting otherwise in the future. But the killing of innocents, Holmes says, is always unjust. So no war can ever be fought justly, regardless of the nature of the goal sought after, such as national defence from an aggressor's attack. The very activities needed to fight wars are intrinsically corrupt, and cannot be redeemed by the putative justice of the ends they are aimed at. How is a just war theorist to respond to this DP challenge?

Some respond by casting doubt on the concept of innocence in wartime. But a just war theorist subscribing to the rule of non-combatant immunity will neither want, nor logically be at liberty, to argue in this fashion. It is hard to see, for example, how infants could be anything other than innocent during a war, and as such entitled not to be made the object of direct and intentional attack. It is only those who, in Walzer's phrase, are "involved in harming us" - i.e. those who pose serious threats to our lives and rights - that we can justly target in a direct and intentional fashion during wartime.

The more appropriate just war response invokes, alongside Walzer, the doctrine of double effect (or DDE). The DDE, invented by Aquinas, is a complex idea. In spite of its apparent technicality, though, the DDE is closely related to our ordinary ways of thinking about moral life. The DDE assumes the

following scenario: agent X is considering performing an action T, which X foresees will produce both good/moral/just effects J and bad/immoral/unjust effects U. The DDE permits X to perform T only if: 1) T is otherwise permissible; 2) X only intends J and not U; 3) U is not a means to J; and 4) the goodness of J is worth, or is proportionately greater than, the badness of U. Assume now that X is a country and T is war. The government of X, contemplating war in response to an attack by aggressor country Y, foresees that, should it embark on war to defend itself, civilian casualties will result, probably in both X and Y. The DDE stipulates that X may launch into this defensive (and thus otherwise permissible) war only if: 1) X does not intend the resulting civilian casualties but rather aims only at defending itself and its people; 2) such casualties are not themselves the means whereby X's end is achieved; and 3) the importance of X's defending itself and its people from Y's aggression is proportionately greater than the badness of the resulting civilian casualties. The DDE, in making these claims, refers to common shared principles regarding the moral importance of intent, of appealing to better expected consequences, and insisting that bad not be done so that good may follow from it.

Just war theorists claim that civilians are not entitled to absolute immunity from attack during wartime. Civilians are owed neither more nor less than what Walzer calls "due care" from the belligerent governments that they not be made casualties of the war action in question. "Due care" involves fighting only in certain ways, applying limited force to specific targets. But does this just war claim simply beg the question against the latest DP principle? DPs insist on absolute immunity for civilians, which in our world would result in banning warfare, whereas just war theorists, acknowledging the threat, seem to dodge it by re-defining the immunity to which civilians are entitled, demoting it to mere "due care." Despite appearances, it is not question-begging but principled disagreement which roots the difference. Just war theorists will argue that civilians cannot be entitled to absolute immunity because that would outlaw all warfare. But outlawing all warfare would ignore both the responsibility for interstate aggression and the implicit entitlement of a state to use necessary means (including armed force) to secure the lives and rights of its citizens from serious and standard threats to them. In the real world, it is neither reasonable nor fair to require a political community not to avail itself of the most effective means available for resisting an aggressive invasion which threatens the lives and rights of its citizens. It is simply not reasonable to require a state to stand down while the aggression of another state wreaks havoc - murder and mayhem - upon its people.

This is not a complete defeat for DP, merely a suggestion of how such defeat might be sought. In my view, DP constitutes the most formidable moral challenge to just war theory (whereas prescriptive realism constitutes the most formidable prudential challenge to just war theory). Suffice it for our purposes to say that the DDE is the just war principle most frequently employed to defeat the DP pacifist's assertion that it is always wrong to kill innocent human beings. Just war theorists prefer to substitute, for this DP claim, the following proposition: what is always wrong, both in peace and war, is to kill innocent human beings intentionally and deliberately. Unintended, collateral civilian casualties can be excused during the prosecution of an otherwise just war, wherein the end is the repulsion of aggression and the means are aimed at legitimate military targets.

Conclusion

This entry provides a sample of the rich and controversial argumentation surrounding philosophical discourse on war. This discourse is dominated by three major traditions of thought: just war theory; realism; and pacifism. The interaction between these three traditions structures the contemporary discussion of wartime issues, at the same time as it fuels fascinating debate about them. While just war theory occupies an especially large and influential space within the discourse, its realist and pacifist alternatives endure as provocative challenges to the philosophical mainstream which it represents.

Bibliography

All the works cited in this entry, plus relevant other works, are listed below. It may be helpful to first locate and emphasize some of the major and most influential sources.

Just war theory is the dominant tradition on the ethics of war and peace. For scholarship on the history and development of just war theory, consult the works of James T. Johnson. Hugo Grotius is often cited as the most formidable classical just war theorist. A translation of his works can be found in J. Scott's edition of *Classics of International Law*. The major contemporary statement of just war theory remains Michael Walzer's *Just and Unjust Wars*. For other contemporary statements, see the works of R. Regan; W.V. O'Brien; J.B. Elshtain; and B. Orend. Works critical of just war theory can be found in the pacifist and realist tracts below.

Other important articles on particular aspects of just war theory include: on *jus ad bellum*, D. Luban, "Just War and Human Rights"; on *jus in bello*, T. Nagel's "War and Massacre" and R. Fullinwinder's "War and Innocence"; and on *jus post bellum*, Kant's "Perpetual Peace", in his *Political Writings* and B. Orend's "Terminating War and Establishing Global Governance".

Hans Morgenthau's *Politics Among Nations* remains an often-cited defense of realism, as does G. Kennan's *Realities of American Foreign Policy*. Henry Kissinger's *Diplomacy* provides the same outlook in perhaps more accessible form. Two of the most focused and effective criticisms of the realist approach to war occur at: Chapter 1 of Walzer's *Just and Unjust Wars*; and Chapters 1-3 of R. Holmes' *On War and Morality*.

The three best contemporary, secular works defending pacifism are: R. Holmes, *On War and Morality*; J. Teichman, *Pacifism and the Just War*; and R. Norman, *Ethics, Killing and War*. Two renowned critical essays on pacifism, both reprinted in R. Wasserstrom, ed. *War and Morality* are G.E.M. Anscombe's "War and Murder" and Jan Narveson's "Pacifism: A Philosophical Analysis".

One prominent writer on the philosophy of war who resists easy classifcation into any of these categories is Carl von Clausewitz. Clausewitz wrote *On War*, one of the most influential general sources, cited by soldiers and statesmen as often as by philosophers or international lawyers. M. Gelven's *War and Existence* is an interesting contemporary piece on the meaning and experience of war, with a Clausewitzian flavor to it.

Feminist Ethics

Feminist Ethics is an attempt to revise, reformulate, or rethink those aspects of traditional western ethics that depreciate or devalue women's moral experience. Among others, feminist philosopher Alison Jaggar faults traditional western ethics for failing women in five related ways. First, it shows little concern for women's as opposed to men's interests and rights. Second, it dismisses as morally uninteresting the problems that arise in the so-called private world, the realm in which women cook, clean, and care for the young, the old, and the sick. Third, it suggests that, on the average, women are not as morally developed as men. Fourth, it overvalues culturally masculine traits like independence, autonomy, separation, mind, reason, culture, transcendence, war, and death, and undervalues culturally feminine traits like interdependence, community, connection, body, emotion, nature, immanence, peace, and life. Fifth, and finally, it favors culturally masculine ways of moral reasoning that emphasize rules, universality, and impartiality over culturally feminine ways of moral reasoning that emphasize relationships, particularity, and partiality (Jaggar, "Feminist Ethics," 1992).

Feminists have developed a wide variety of women-centered approaches to ethics, including those labeled "feminine," "maternal," and "lesbian." Each of these approaches to ethics highlights the differences between men's and women's respective situations in life- biological and social; provides strategies for dealing with issues that arise in private as well as public life; and offers action guides intended to undermine rather than bolster the present systematic subordination of women (Jaggar, "Feminist Ethics," 1992). Considered together the overall aim of all feminist approaches to ethics, irrespective of their specific labels, is to create a gender-equal ethics, a moral theory that generates non-sexist moral principles, policies, and practices.

Feminist Ethics: Historical Background

Feminist approaches to ethics, as well as debates about the allegedly gendered nature of morality, are not contemporary developments. A variety of eighteenth and nineteenth-century thinkers like Mary Wollstonecraft, John Stuart Mill, Catherine Beecher, Charlotte Perkins Gilman, and Elizabeth Cady Stanton all discussed what is probably best termed "women's morality." Each of these thinkers pondered questions such as: Are women's psychological feminine traits all natural? Or is it only women's *positive* psychological feminine traits that are natural, their *negative* ones being somehow socially-constructed? Is there a gender neutral standard available to separate women's good or positive traits from women's bad or negative traits? If moral virtues as well as psychological traits are connected with one's affective as well as cognitive dimensions, indeed with one's physiology as Aristotle and Aquinas suggested, shouldn't we expect men and women to manifest different moral virtues as well as different psychological traits? Should all individuals be urged to cultivate precisely the same set of psychological traits and moral virtues, or should there be room for trait and virtue specialization, provided that this specialization does not split down gender lines? Even if this specialization is split down gender lines?

With respect to the kind of questions about "women's morality" posed above, the eighteenth-century thinker Mary Wollstonecraft answered that women's and men's moralities are fundamentally the same. Although she did not use terms such as "socially-constructed gender roles," Wollstonecraft denied that women are *by nature* more pleasure seeking than men. She reasoned that if men were confined to the same cages women find themselves locked in, as are low-ranking military men, for example, they would develop the same kind of weak characters women develop. Denied the chance to develop their rational powers, to become moral persons who have concerns, causes, and commitments over and beyond their own physical and psychological pleasure, men as well as women would become overly "emotional," a condition Wollstonecraft associated with hypersensitivity, extreme narcissism, and excessive self indulgence (Wollstonecraft, A Vindication of the Rights of Women, 1988).

Because she regarded the ability to reason rather than the capacity to feel as the characteristic that distinguishes humans from brutes, Wollstonecraft contrasted manners, such as any automaton might master, with morals, which requires an educated understanding. Whereas society teaches men morals, it teaches women manners. More specifically, society encourages women to cultivate negative psychological traits like "cunning," "vanity," and "immaturity," all of which impede the development of more positive psychological traits. Even worse, society twists what could be woman's genuine virtue into vices. Wollstonecraft specifically claimed that when strong women practice gentleness, it is a grand, even godly, virtue; but when weak women practice it, it is a demeaning, even subhuman, vice. The positive psychological trait of gentleness is transformed into the negative psychological trait of obsequiousness "when it is the submissive demeanor of dependence, the support of weakness that loves, because it wants protection; and is forebearing because it must silently endure injuries; smiling under the lash at which it dare not snarl" (Wollstonecraft, A Vindication of the Rights of Women, p. 117).

Distressed by her female contemporaries' negative psychological traits, Wollstonecraft concluded that the quickest way for women to be regarded as moral is for them to become like men--that is, for women to

display the psychological traits usually associated with men. Yet, just because Wollstonecraft lamented women's moral deficiencies does not mean that she totally blamed women for not being as good as they possibly could be. On the contrary, she claimed that because women are politically and economically oppressed, they do not have the material means necessary to develop their moral potential.

Debates about what makes a character good and a personality socially acceptable did not end with Mary Wollstonecraft. The passing of time can certainly result in changes, for by the nineteenth-century women were regarded as more moral (though also as less intellectual) than men, a view that disturbed utilitarian philosopher John Stuart Mill. As he saw it virtue (as well as intellect) has nothing to do with gender. Society is wrong, he said to set up an ethical double standard according to which women's morality is to be assessed differently than men's morality. Reflecting further on women's alleged moral superiority, Mill concluded that women's "moral nature" is not the result of innate female propensities but of systematic social conditioning. To praise women on account of their great "virtue" is merely to compliment patriarchal society for having inculcated in women those psychological traits that serve to maintain it. Women are taught to live for and sacrifice for others; to always give and never receive; to submit, yield and obey; to be long-suffering. Their "virtue" is not of their own doing; society imposes it upon them (J.S. Mill, The Subjection of Women, 1970).

In contrast to Wollstonecraft and Mill, other eighteenth-and nineteenth-century thinkers denied that virtue is one. Instead, they forwarded either a separate-but-equal theory of virtue according to which male and female virtues are simply different, or a separate-and unequal theory of virtue according to which female virtue is ultimately better than male virtue. Significantly, this diverse group of thinkers disagreed among themselves whether the characteristics typically associated with women (nurturance, empathy, compassion, self sacrifice, kindness) are (1) full-fledged moral virtues to be developed by men as well as by women; (2) *positive* psychological traits to be developed by women alone; (3) or *negative* psychological traits to be developed neither by women nor men.

Catherine Beecher belonged to this group of thinkers. Even though she believed that women's place is in the home, she did not believe that women's work is unimportant. On the contrary, she believed that women's work--the creation and maintenance of homes in which moral virtue thrives--is absolutely essential for society's well-being. She reasoned that men would lose their *raison d'etre* for working if they lacked loving families and well-ordered homes. In an effort to make certain that society would indeed value women's work *at least* as much as men's work, Beecher and her sister Harriet created the discipline of "domestic science." They stressed that women's work requires much intelligence and skill; that it is not easy to manage a household properly. They also emphasized that women's most important work is to make society Christlike--that is, submissive, self-sacrificial, and benevolent. Sheltered safely in the private realm, where they are largely insulated from the siren calls of wealth, power, and prestige that pervade the public sphere of politics and economics, women are supposedly better situated to cultivate what Beecher and her sister termed the Christlike virtue of "self-denying benevolence." The better that women are, the better that everyone else will be. Convinced that women were somehow responsible for the moral rectitude of men and children, it never occurred to Beecher to ask herself why Christ, a man, had selected women rather than men to specialize in the virtue of self-denying benevolence (Beecher and Stowe, The American Woman's Home, 1971).

Writing around the time Beecher wrote, Elizabeth Cady Stanton also found differences between women's and men's moralities. Stanton's discussion of this already knotty topic is complicated by her apparent inability to decide whether female and male virtue and vice are more the product of nurture or nature. But whether her final view is that men's and women's diverging virtues and vices are the result of social manipulation or biological imperative, Stanton consistently maintained that what she regarded as men's inferior set of morals have set the standard for behavior in the public world. Women's set of morals, which Stanton regarded as superior to men's, have been either suppressed or ignored to the detriment of the public world. The solution to this unfortunate state of affairs, said Stanton, is a relatively simple one: permit, indeed require, women to enter the public world. Humankind cannot afford to leave women, as Beecher would, in the private world, struggling to exert their good influence there and only there. (Buhle and Buhle, eds., The Concise History of Women's Suffrage, 1988).

Yet, despite the fact that like Beecher, Stanton valued women's self-denying benevolence, she believed there was a higher virtue for women to develop: namely, self-development. In the course of interpreting a biblical passage in which Jesus praises a poor widow for her charitable actions, Stanton observed that an oppressed person cannot always afford to be so giving--not without destroying herself. Agreeing that the poor widow's charitable actions were indeed laudatory, Stanton nonetheless cautioned women that women's self-sacrifice may effectively perpetuate women's second-class status. Although the duty of self-sacrifice is morally required in the abstract, "ought" implies can in the concrete. Because few women in a patriarchal society have the political and economic means to practice benevolence without men taking advantage of them, they cannot always afford to be other-directed; sometimes they have to be self-centered.

Although she probably did not think of herself as extending Stanton's line of reasoning, Charlotte Perkins Gilman portrayed on all-female society in which the women are able to serve each other and their daughters (produced through parthenogenesis) without anyone being "sacrificed" in the process. Herland is a child-centered society of mothers in which the lines between the so-called private and public realms have been radically redrawn. The women of Herland are at ease in the halls of justice and centers of trade as well as in the nurseries and schools. Competitive individualistic approaches to life, with their hostility toward connectedness, disappear in Herland, and its women are able to relate to each other without dominating each other.

No wonder that the three American explorers--Terry, Jeff and Van --who stumble on Herland are shocked and confused. Before they arrive, they joke about the mythical land, assuming that there must be men it, since women could not possibly cooperate well enough, or be competent enough, to run a country. When they see how successfully Herland is run, only one of them, Van, praises its all female population as a group of exemplary human beings whose behavior all persons, male as well as female, should seek to emulate. As he sees it, the women of Herland exhibit virtues that are neither feminine nor masculine, but simply fully human (Gilman, Herland, 1979).
Of course, Herland is a fictional, ideal-world in which imagined social, economic, and ideological conditions permit women to develop in morally good as well as psychological healthy ways. Conditions are quite different for women in our nonfictional, real-world. In Women and Economics (1966), Gilman

wrote that to the degree women are dependent on men for support, women will be known for their blind faith, complete submission, and servile self-sacrifice, and men will be known for their stubborn opinions, dominating actions, and arrogant selfishness. Only when women are men's economic equals will women and men both be able to develop truly human moral virtue, the perfect blend of pride and humility: namely, self-respect.

Feminine Approaches to Ethics

Clearly, women-centered thinkers in the eighteenth and nineteenth centuries tended to think of morality as gendered. Since women-centered thinkers in the twentieth century also tend to think of morality as gendered, it is important to determine whether a gendered conception of morality is indeed correct. Such a determination cannot be made, however, unless the ontological and epistemological assumptions of those who advocate feminine, maternal, feminist, and/or lesbian approaches to ethics are first articulated. Apparently, most of the thinkers who have forwarded a woman-centered approach to ethics have rejected the ontological assumptions that the more separate the self is from others, the more fully-developed that self is; and the epistemological assumption that the more universal, abstract, impartial, and rational knowledge is, the more closely it mirrors reality. In place of these assumptions, they have instead embraced the ontological assumption that the more connected the self is to others, the better that self is, and the epistemological assumption that the more particular, concrete, partial, and emotional knowledge is, the more likely it represents the world as it truly is. Thus, it is not surprising that "communal woman" rather than "autonomous man" appears in almost every woman-centered approach to ethics, but that she stresses a different message about "women's morality" depending on her particular guise: feminine, maternal, feminist, or lesbian.

Proponents of feminine approaches to ethics like Carol Gilligan and Nel Noddings stress that traditional western moral theories, principles, practices, and policies are deficient to the degree that they lack, ignore, trivialize, or demean those traits of personality and virtues of character that are culturally associated with women. Gilligan presents her work as a response to the Freudian notion that whereas men have a well-developed moral sense, women do not. Freud attributed women's supposed moral inferiority to girls' psychosexual development. Whereas boys break their attachment to their mothers for fear of being castrated by their fathers if they don't, girls remain emotionally tied to their mothers since castration threats have no power over them. As a result of this state of affairs, girls are supposedly much slower than boys to develop a sense of themselves as autonomous moral agents personally responsible for the consequences of their actions or inactions; as persons who must obey society's rules or face its punishments.

According to Gilligan, Freud is simply one of many western psychologists and philosophers who have seen women's moral inferiority where, in Gilligan's estimation, they should have instead seen simply women's moral difference from men. Gilligan singles out her former mentor, educational psychologist and moralist Lawrence Kohlberg for particular criticism. Kohlberg claimed that moral development is a six-stage process. Stage One is the punishment and obedience orientation. To avoid the "stick" of punishment and/or to receive the "carrot" of a reward, children do as they are told. Stage Two is "the

instrumental relativist orientation." Based on a limited principle of reciprocity- You scratch my back and I'll scratch yours--children meet others' needs only if others meet their needs. Stage Three is the "good boy-nice girl" orientation. Adolescents conform to prevailing norms to secure others' approval and love. Stage Four is the law and order orientation. Adolescents begin to do their duty, show respect for authority, and maintain the given social order to secure others' admiration and respect for them as honorable, law abiding citizens. Stage Five is the social-contract legalistic orientation. Adults adopt an essentially utilitarian moral point of view according to which individuals are permitted to do as they please, provided they refrain from harming other people in the process. Stage Six is the universal ethical principle orientation. Adults adopt an essentially Kantian moral perspective that seeks to transcend and judge all conventional moralities. Adults are no longer ruled by self-interest, the opinion of others, or the fear of legal punishment, but by self-legislated and self-imposed universal principles such as those of justice, reciprocity, and respect for the dignity of human persons (Kohlberg in Mischel, ed., Cognitive Development and Epistemology, 1971).

Although Gilligan concedes that Kohlberg's six-stage scale appeals to many people schooled in traditional western ethics, she insists that the popularity of a theory of moral development is not an index of its truth. She asks whether Kohlberg's six stages of moral developments are indeed: (1) universal, (2) invariant (a always precedes b, b always precedes c, etc.), and (3) hierarchical (b is "more adequate" than a, c is "more adequate" than b, etc.). In particular, she asks why, in the Kohlbergian work with which she is most familiar, women rarely climb past Stage Three, whereas men routinely ascend to Stages Four and even Five? Does this gender difference mean that women are less morally developed than men are? Or does it instead mean that there is something wrong with Kohlberg's methodology--some bias that permits men to achieve higher moral development scores than women?

Gilligan answers that Kohlberg's methodology is male-biased. Its "ears" are tuned to male, not female, moral voices. Thus, it fails to register the different voice Gilligan claims to have first heard in her study of twenty-nine women reflecting on their abortion decisions. This moral voice, insists Gilligan, speaks a language of care stressing relationships and responsibilities, a language that is largely unintelligible to Kohlbergian researchers, who speak the dominant moral language of western ethical tradition--namely, a language of justice emphasizing rights and rules.

Although Gilligan emphasizes that the languages of care and justice are not gender correlated in any iron-clad way, with all women speaking only the language of care and all men speaking only the language of justice, the examples she uses tend to belie her important disclaimer. In her foundational abortion study, she shows only women moving in and out of the three moral frames of reference that constitute her relational ethics: Level One in which women overemphasize the interests of their selves; Level Two in which women overemphasize others' interests; and Level Three in which women weave their own interests together with those of others. Thus, a woman at Level One would make her abortion decision in terms of what is best for herself, at Level Two in terms of what is best for others, and at Level Three in terms of what is best for herself and others considered as a relational unit (Gilligan, In a Different Voice, 1982).

As described so far, Gilligan's Levels seem no more an account of human moral development than

Kohlberg's Stages, with Kohlberg focusing on men's moral experience, and Gilligan on women's. Openly admitting this point, Gilligan has begun to study men's as well as women's moral experience. Her central aim is to expose the ways in which the U.S. society continues to muffle boys' and mens' sensitivity, encouraging them to be less than caring and fully nurturant human persons. Gilligan stresses that unlike today's women who speak the moral language of justice and rights nearly as fluently as the moral language of care and relationship, today's boys and men remain largely unable to articulate their moral concerns in anything other than the moral language of justice and rights.

One index of the importance of Gilligan's work is not only the number of thinkers who have applied her insights to their areas of expertise but also the number of thinkers who have taken her work seriously enough to critique it. To date Gilligan's critics have focused either on the relationship between justice and care, considered as two, gender-neutral perspectives on morality, or on the fact, that women are culturally associated with care and men are culturally associated with justice.

Critics who adopt the first strategy are primarily non-feminist critics. Some of them argue that even if care is a moral virtue and not simply a pleasing psychological trait that some people happen to have, it is a less essential moral virtue than justice. Among the statements such non feminist critics make is that it is better to act out of a general moral principle like "aid the needy" than a particular caring feeling like human heartedness because principles are more reliable and less ephemeral than feelings; and (2) that, when justice and care conflict, considerations of impartiality must trump considerations of partiality: my children's fundamental rights and basic needs are neither more nor less important than anyone else's children's.

Other non-feminist critics fault Gilligan not for claiming that care is a genuine moral virtue equal in value to justice, but for suggesting that this is ethical "news." These critics stress that two, not one, basic principles of prima facie obligation, benevolence and justice, have always ruled traditional western ethics. From benevolence flow the principle of utility, the principle of not harming anyone, and the principle of not interfering with another's liberty. From justice flows the principles of equality of respect and consideration and equality before the law. But in defense of Gilligan, what some traditional western philosophers mean by "benevolence" may not be what Gilligan means by "care." Philosopher Lawrence A. Blum invites us to consider the specific principle "Protect one's children from harm," a principle that flows from the general principle of benevolence. As Blum sees it, all sorts of parents subscribe to this specific principle, but only those parents who are caring--that is, sensitive to and aware of their children's unique interests and needs--will not only know when and how to meet the terms of the principle, but actually be motivated to do so. Although most traditional western philosophers agree with Blum that caring parents are more likely to actually act benevolently than uncaring parents are, they do not agree with him that only caring parents are capable of so acting. Instead they insist that a formal sense of duty, whether or not it is accompanied by caring feelings, is sufficient to generate moral action. Like many ethicists who are developing feminine approaches to ethics, however, Blum believes that the person who would be moral must do more than merely obey the letter of the law. He or she must also be infused with the proper spirit--the appropriate emotions, sentiments, feelings--to perform an entirely morally worthy action (Blum, Friendship, Altruism, and Morality, 1980).

In addition to the non-feminist criticisms that have been raised against Gilligan, several feminist criticisms have been directed against her work. Of these criticisms, the most powerful worries that even if women are better carers than men, it may still be epistemically, ethically, and politically imprudent to associate women with the value of care. To link women with caring is to promote the view that because women can care, they should care no matter the cost to themselves.

In Femininity and Domination (1990), feminist critic Sandra Lee Bartky argues that women's experience of feeding men's egos and tending men's wounds ultimately disempowers women. She notes that the kind of emotional work practiced by women in some service-oriented occupations often causes these women to lose touch with their own emotional base. For example, to pay a person to be "relentlessly cheerful"--to smile at even the most verbally-abusive and unreasonably demanding customer--means paying a person to feign a certain set of emotions. Yet, a person can pretend to be happy only so many times before that person forgets how it feels to be genuinely or authentically happy.

Bartky concedes that women insist that, far from draining them; the emotional work they do energizes them. Indeed many wives and mothers claim the experience of caring for their husbands and children is meaning-giving and self-validating. The better carers they become, they more they view themselves as the family's or marriage's indispensable backbone. Yet subjective feelings of empowerment are not the same as the objective reality of actually having power, says Bartky. She explains how women's androcentric emotional work can work against women distorting women's moral integrity. Bartky points to Teresa Stangl, wife of Fritz Stangl, Kommandant of Treblinka. Despite the fact that her husband's monstrous activities horrified her, she continued to "feed" and "tend" him dutifully, even lovingly. In doing so, however, she played footloose and fancy free with her own soul, for a woman cannot remain silent about evil and still expect to keep her goodness entirely intact. Since horror perpetrated by a loved one is still horror, women need to analyze "the pitfalls and temptations of caregiving itself" before they embrace as ethics of care wholeheartedly (Bartky, Femininity and Domination, 1990).

Mullet reinforces Bartky's fears about a feminine ethics of care. She distinguishes between "distortion of caring" on the one hand and "undistorted caring" one the other. According to Mullet, a person cannot truly care for someone if she is economically, socially, and/or psychologically coerced to do so. Thus, genuine, or fully authentic caring cannot occur, for example, under conditions characterized by male domination and female subordination. Only under conditions of sexual equality and freedom can women care for men without men diminishing, disempowering, and/or disregarding them. As long as men demand and expect more caring from women than women demand and expect from men, both sexes will remain morally impoverished. Neither men nor women will be able to authentically care.

Bartky's and Mullet's interpretation of care are far too pessimistic in the opinion of the thinkers--and there are more than Gilligan--who favor "feminine" approaches to ethics. They stress that even if it is dangerous for women to care in a patriarchal society, care remains part of the solution as well as part of the problem. Care's conflicted status calls for the development of a more robust ethics of care, not for the abandonment of care.

In response to the summons for a sound and complete ethics of care, Nel Noddings has developed a

feminine, relational ethics. For Noddings, ethics is about particular relationships between two parties, the "one-caring" and the "cared-for." Caring is not simply a matter of feeling favorably disposed towards humankind in general, of being concerned about people with whom one has no concrete connection. I can't be said to care about the children in Somalia as much as I care for my own two sons. Real care requires actual encounters with specific individuals; it cannot be accomplished through good intentions alone.

Noddings claims that as children we act from a natural caring that moves us to help others simply because we want to. Later, when society distorts our wants and makes it harder for us to care, the deliberateness of ethical caring supplements the spontaneity of natural caring. Nevertheless, says Noddings, natural caring remains somehow better than ethical caring--and certainly the condition of its possibility.

Although Noddings insists that men as well as women can and should be carers, most of her examples of caring involve women, many of whom seem to care too much--that is, to the point of imperiling their own identity, integrity, and even survival. Although Noddings protests that, in her estimation, it is moral for the one-caring to care for herself, she conveys the impression that the one caring should care for herself only insomuch as her self-caring enables her to care for others better. Thus, the one-caring's self-caring is actually a disguised form of other-directed care.

Maternal Approaches to Ethics

Closely related to feminine approaches to ethics are so-called maternal approaches to ethics. Maternal thinkers like Sara Ruddick, Virginia Held, and Caroline Whitbeck affirm the feminine psychological traits and moral virtues that society associates with women. As they see it, a truly gender-equal ethics would not favor paradigms, such as the contract model, that speak much more to men's experience in the public world than anyone's, but especially women's and children's experience in the private world. Most of our relationships, say Ruddick, Held, and Whitbeck, are not between equally-informed and equally powerful persons, but between unequal persons. When a parent relates to a child, or a physician to a patient, or a self-confident adolescent to a depressed and distraught friend, they do not relate as two tycoons do during a business negotiation, but as two individuals with very different and amorphous strengths and weaknesses. Ethics should be built on a model that fits life as most people live it on an everyday basis. Not the concepts, metaphors, and images associated with the practice of contracting, but those associated with the practice of parenting (especially mothering) better express the dynamics of moral life.

In her maternal approach to ethics, Ruddick claims that society should not trivialize what she terms "maternal practice." Like any human practice, maternal practice has its own form of thinking with a vocabulary and logic peculiar to it, and its own aims and goals. In the case of maternal thinking, these aims and goals consist in the preservation, growth, and acceptability of one's children (Ruddick, Maternal Thinking, 1989).

Preserving the life of a child is the "constitutive maternal act." Infants are totally vulnerable. They simply will not survive unless their caretakers feed, clothe, and shelter them. Ruddick gives the example of Julie,

an exhausted young mother with a very demanding infant. Having reached her physical and psychological limits, Julie pictures herself killing her baby daughter. Horrified by her own thought, Julie spends the night riding a city bus, her baby in her arms. She reasons that, as long as they remain in the public eye, she will not harm her baby.

Ruddick tells Julie's story to stress how difficult it is for a mother to meet her child's material needs. Not every mother grows so run-down and desperate that she has to take steps to ensure that she will not slaughter her child. However, even under relatively ideal circumstances, most mothers do have days when they wish they were not mothers. In order to be able to "preserve" their children on these bad days, says Ruddick, mothers should cultivate the intellectual virtue of scrutiny and the moral virtues of humility and cheerfulness. Armed with these three virtues, mothers will be able to roll with the punches that life delivers to children and adults alike.

The second dimension of Ruddick's maternal-practice is *fostering* children's growth. Whatever fostering a child's growth may mean, it does not mean the act of imposing an already written script on one's child. A mother should not hand book entitled The Tale of the Perfect Child to her daughter insisting that she enact in her imperfect life scenes of the "perfect child's" *perfect* life. Rather, a mother should tell her daughter, realistic, compassionate, and delightful "maternal stories"--the kind of stories that will enable her daughter to realize that she is lovable despite her weaknesses.

The third and final dimension of Ruddick's maternal practice is *training*. For the most part, mothers work hard to socialize their children--to help them become committed and concerned citizens as opposed to members of either armed gangs or opium dens. On occasion, however, mothers will demur from "properly" socializing their children. For example, they will refuse to fit their children's vulnerable bodies into military uniforms, or diet them into designer jeans, or dress them for success in the so-called "dog-eat-dog" world. In a patriarchal society--that is, an overly competitive, hierarchical, and individualistic society-mothers may find themselves caught between the external demands of patriarchy on the one hand and their own inner conviction that these external demands are dehumanizing ones on the other. If a mother trains her son to dress for success, he may become both the chief executive officer of a large firm and a very mean-spirited human being. In contrast, if she refuses to teach her son the lessons of conformity, he may become both an exemplary human being and someone whom patriarchy labels "a loser." Like all mothers, says Ruddick, this mother must decide whether her maternal values or those of the larger society should guide her child-training practices.

Grounding the work of preserving, fostering the growth of, and training children, says Ruddick, is the metavirtue of "attentive love." This metavirtue, which is at once cognitive and affective, rational and emotional, enables mothers to look their children in the eyes and not be shocked, horrified, or appalled by what they see. Indeed, among the several characteristics that distinguish maternal thinkers from nonmaternal thinkers is their utter realism. Mothers who love their children *inattentively* let their fantasies blind them. They do not see their children as they actually are. Rather they see their children as they could perhaps be: the fulfillment of their dreams. In contrast to these mothers, mothers who love their children attentively accept their children for whom they are, working within their physical and psychological limits.

Ruddick's ultimate goal is not simply to develop a phenomenology of maternal practice. Rather, she wants to demonstrate that anyone, male or female, who engages in maternal practice will come to think like a mother in the public world as well as the private world. If men spent as much time rearing children as women do, men as well as women would come to think and see what mothers think and see. People who think and see like mothers make connections, for example, between war in the abstract and war in the concrete. For them, war is not about winning, defending one's way of life, and establishing one's position of power. Instead, it is about destroying that boy or girl whom one has spent years preserving, nurturing, and training: a unique human person who cannot be replaced. In sum, for a maternal thinker, war is about death--about canceling out the "product(s)" of maternal practice.

Held approaches maternal practice from a somewhat different perspective than Ruddick does. She suggests that because women have spent so much of their time mothering, they should develop moral theories that fit the kind of relationships and activities that characterize the *private* rather than the *public* domain. Although Held knows that not all women live in the private world, and although she does not believe that all women are determined by nature to have a distinctive set of moral experiences, she nonetheless claims that a sizable gap exists between women's and men's moral experience. It concerns her that traditional western ethics not only discounts *women's* morality but presents what amounts to *men's* morality as *gender neutral* morality. She claims that if traditional western ethics really gender-neutral, however, it would not favor paradigms--for example, the contract model --that speak much more to men's experience than to women's. In Held's estimation, too many traditional western ethicists bless a human relationship as moral to the degree that it serves the separate interests of individual rational contractors. Yet life is about more than conflict, competition, and controversy--about getting what one wants. It is, as mothering persons know, also about cooperation, consensus, and community- about meeting other people's needs. Held speculates that were the relationship between a mothering person and a child, rather than the relationship between two rational contractors, the paradigm for good human relationships, society might look very different (Held, "Feminism and Moral Theory," 1987).

Held concedes, however, that the kind of relationships that exists between mothering persons and children can be just as oppressive--indeed, even *more* oppressive--than the relationship that exist between two rational contractors. For example, it is sometimes harder to recognize abuses of power in a father-son relationship than in an employer-employee relationship. A father's subtle pressure that his artistic son give up the theater and go to law school may not be as evident an abuse of power as the executive who steals his assistant's ideas and presents them as his own, but both situations exploit and undercut the autonomy of the two relatively powerless agents involved.

Held also admits that, in their attempt to celebrate the positive features of maternal ethics, some maternal thinkers unnecessarily reject the valuable features of traditional ethics. Just because a maternal ethics can handle issues that exceed the "moral minimum" of taking everyone's rights seriously does not mean that it should dispense with this "moral minimum." Mothering persons must be fair as well as compassionate; rational as well as emotional; able to make generalizations about human relations as well as to articulate their unique features. A maternal thinker who says that no two human relationships are ever alike invites moral chaos. Like principles, relationships can be qualified as good, better, or best (bad, worse, or worst),

and that which is subject to *qualification* is also subject to *evaluation*. In the same way that we can ask what makes a principle good or bad, we can ask what makes a relationship good or bad.

Unlike some maternal thinkers, Held believes that men as well as women can be mothering persons. Just because men cannot bear children does not mean that they cannot rear children. Men as well as women can, indeed should, appropriate the moral outlook of those who care for others. Leaving caregiving to women alone produces *boys* with relatively combative and insensitive personalities. Because bellicose, unfeeling boys usually mature into bellicose, unfeeling *men* in positions of power, Held claims that human survival may depend on our ability to reorganize the way we parent. Equal parenting, based on men's and women's equal respect and consideration for each other's equal rights of self-determination must become the order of the day (Held, "The Obligations of Mothers and Fathers," 1984).

Despite the fact that Held believes that men as well as women can mother, she still indicates that there may be a *qualitative* difference between female mothering and male mothering. The fact that women can *bear* children as well as *rear* children may signal that women are, afterall, more responsible than men for the existence of new persons. She notes that although women need men to begin a pregnancy, they do not need men to end a pregnancy. Through abortion or suicide, women can say a definite "no" to life.

By stressing women's ultimate responsibility for bringing (or not bringing) new persons into existence, Held does not wish to negate her previous point that fathers as well as mothers are obligated to rear children. Because men participate in the creation of life, they should participate in its maintenance. Nevertheless, men's direct role in procreation lasts but a few moments, whereas women's lasts for nine months. The experiences of pregnancy make women especially aware of their procreative role. For example, when a pregnant woman eats, she can focus on the fact that she is, as they old saying goes, "eating for two." If she fails to eat a healthy diet, both she and the fetus will suffer. Likewise, when a pregnant women finally gives birth, she can say to herself, "Through this pain, I bring life into this world." These kinds of experiences are ones that a man can never have. The well-being of the fetus his sperm helped create depends on him only indirectly, and he will probably never be called to physically suffer for his son or daughter as much as his wife (or lover) did on the day she gave birth to their child.

Even if the daily toil of bringing up a child will eventually take a greater toll on a parent than the momentary suffering of giving birth, Held asserts that we should not trivialize the birthing act as if it had no effect whatsoever on subsequent parent-child relationships. In suggesting that biological experiences may influence the attitudes of the mother and father toward the preciousness of a particular child, Held wants to explore the relationship between the kind of feelings women and men have for their children on the one hand and the kind of obligations they have to them on the other. If ethicists assume that "natural" male tendencies like the desire to pursue their own self-interest competively play a role in determining men's moral rights and responsibilities, then they should make the same assumption about "natural" female tendencies like the tendency to center their lives on the well-being of their children. Thus, the fact that mothers shudder at the Biblical account of Abraham, who was willing to kill his son, Isaac, in order to honor God's command, is to be expected. Women who birth children--who preserve, nurture, and train them--are not likely to believe that obeying a command, even a command of God, is more valuable than preserving the very lives of these children. To be sure, from the standpoint of traditional western ethics, a

mother's refusal to subordinate the concrete life of *her* child to the abstract commands of duty or higher law indicates her underdevelopment as a moral agent. Yet, in an age where a blindness to interconnection has led to the destruction of the environment and a perilous buildup of the nuclear arsenal, a focus on connection rather than individualistic rights may indeed not only suggest a higher morality but offer a saving grace in an increasingly chaotic world.

In general Whitbeck offers an interpretation of mothering that, more than Ruddick's or Held's, emphasizes the *biological* facts of motherhood. In fact, Whitbeck suggests that women's "maternal instinct" causes them to notice things about their babies that men do not. Specifically, a mother often feels as vulnerable as an infant throughout her pregnancy, but especially during labor. It is her helplessness--in the sense of losing control of her body during pregnancy, of suffering pain during labor, of feeling weak during the postpartum period- that enables a mother to understand just how dependent her infant is on her. No matter how hard a father tries, he can never experience either a mother's or an infant's helplessness. All he can do is to intellectualize about this experience, sympathizing with it the best he can.

Despite the fact that Whitbeck concedes that men can learn how to mother their children and that women can choose not to mother their children, she nonetheless believes that men's and women's different biological experiences typically affect the *intensity* of their respective attachments to their offspring. The bodily experiences that women have simply because they are women tend to deepen those feelings and attitudes which cause people generally to care for their infants. To the degree that human beings are mind-body unities rather than mind-body dualities, a mother's physical experiences will affect the way she thinks about her children (Whitbeck, "The Maternal Instinct," 1984).

The critics of maternal approaches to ethics, like the critics of feminine approaches to ethics, are of two kinds: nonfeminist and feminist. Nonfeminist critics doubt that any one human relationship either can, or should, serve as the paradigm for all human relationships. As they see it, any human relationship--be it one of husband-wife, parent-child, sibling-sibling, friend-friend, or ruler subject--is simply too specific to provide a general model for how people should treat each and every person with equal respect and consideration. Certainly, relationships between unequals should not serve as the model for relationships between equals or vice versa.

Feminist critics express reservations about maternal approaches to ethics quite similar to those of non-feminist critics. They note that Ruddick herself has some doubts even about her own version of maternal ethics. She worries that she might be over-idealizing mothers, unnecessarily excluding men and nonbiological mothers from maternal work, and underemphasizing the differences that exist among mothers, some of whom find themselves "mothering" under extremely oppressive circumstances.

Stressing that some mothers abuse and neglect their children, that many men and nonbiological mothers are just as good or even better parents than many biological mothers, other feminist critics add the point that the mother-child relationship is a particularly problematic choice for a moral paradigm, freighted as it is with enough patriarchal baggage to weigh down even the strongest of women. Although these feminists critics of maternal approaches to ethics concede that the mother-child relationship is a better model for human and humanizing relationships than the traditional rational-contractor model, they believe that even

better models are available. After all, the mother-child relationship is not the only human relationship that is based more on need than on desire, more on love than on obligation, and more on trust than on fear. Friendship relationships, especially ones based on shared goals and aspirations as well as on having a good time and/or on providing emotional and economic support, offer all that the mother-child relationship offers and more. Held together by tears, laughter, and sweat rather than waivers, subpoenas, and depositions, friendship relations seem to hold out more possibilities for moral development than contractual relations. They are also less imbalanced than mother-child relationships in that the parties to them are equals in the sense that they can give to each other approximately as much as they take from each other (Friedman, What Are Friends For?:Feminist Perspectives on Personal Relationships and Moral Theory, 1990).

Feminist Approaches to Ethics

Given that some feminine and maternal approaches to ethics have feminist aspects, and that most of the thinkers who are developing feminine and/or maternal approaches to ethics regard themselves as feminists, it is challenging to specify what makes an approach to ethics "feminist" as opposed to simply "feminine" and/or "maternal." Clearly, the focus of feminist approaches to ethics does not make them distinctive. Feminine, maternal, and feminist approaches to ethics are all women-centered; they all speak primarily to women about *women's* moral experiences. Rather, feminist approaches to ethics are distinctive because they, far more than their feminine and/or maternal counterparts, are "political" in the sense that *fully* feminist ethicists are committed, first and foremost, to the elimination of women's subordination--and that of other oppressed persons--in all of its manifestations." A feminist approach to ethics asks questions about *power*- that is, about domination and subordination--even before it asks questions about *good* and *evil, care* and *justice*, or maternal and paternal thinking.

Focused as they are on questions about power, those developing fully feminist approaches to ethics offer action guides aimed at subverting rather than reinforcing the present systematic subordination of women. Liberal, Marxist, radical, socialist, multicultural, global, and ecological feminists have each offered a different set of explanations and solutions for this state of affairs. So too have existentialist, psychoanalytic, cultural, and postmodern feminists. Proponents of these varied schools of feminist thought maintain that the destruction of all systems, structures, institutions, and practices that create or maintain invidious power differentials between men and women is the necessary prerequisite for the creation of gender equality.

Liberal feminists charge that the main cause of female subordination is a set of informal rules and formal laws that block women's entrance and/or success in the public world. Excluded from places such as the academy, the forum, the marketplace, and the operating room, women cannot reach their potential. Women cannot become men's full equals until society grants women the same educational opportunities and political rights it grants men.

Marxist feminists disagree with liberal feminists. They argue that it is impossible for any oppressed person, especially a female one, to prosper personally and professionally in a class society. The only

effective way to end women's subordination to men is to replace the capitalist system with a socialist system in which both women and men are paid fair wages for their work. Women must be men's economic as well as educational and political equals before they can be as powerful as men.

Disagreeing with both Marxist and liberal feminists, *radical feminists* claim that the primary causes of women's subordination to men are women's sexual and reproductive roles and responsibilities. Radical feminists demand an end to all systems and structures that in any way restrict women's sexual preferences and procreative choices. Unless women become truly free to have or not have children, to love or not love men, women will remain men's subordinates.

Seeing wisdom in both radical and Marxist feminist ideas, *socialist feminists* attempt to weave these separate streams of thought into a coherent whole. For example, in Women's Estate, Juliet Mitchell argues that four structures *overdetermine* women's condition: production, reproduction, sexuality, and the socialization of children. A woman's status and function in *all* of these structures must change if she is to be a man's equal. Furthermore, as Mitchell adds in Psychoanalysis and Feminism, a woman's interior world, her psyche, must also be transformed;

for unless a woman is convinced of her own value, no change in her exterior world can totally liberate her.

Multicultural feminists generally affirm socialist feminist thought, but they believe it is inattentive to issues of race and ethnicity. They note, for example, that U.S. "white" culture does not praise the physical attractiveness of African American women in a way that validates the natural arrangement of black facial features and bodies, but only insofar as they look white with straightened hair, very light brown skin and thin figures. Thus, African-American women are doubly oppressed. Not only are they subject to gender discrimination in its many forms, but racial discrimination as well.

Although *global feminists* praise the ways in which multiculturalist feminists have amplified socialist feminist thought, they nonetheless regard even this enriched discussion of women's oppression as incomplete. All too often, feminists focus in a nearly exclusive manner on the gender politics of their own nation. Thus, while U.S. feminists struggle to formulate laws to prevent sexual harassment and date rape, thousands of women in Central America, for example, are sexually tortured on account of their own, their fathers', their husbands', or their sons' political beliefs. Similarly, while U.S. feminists debate the extent to which contraceptives ought to be funded by the government or distributed in public schools, women in many Asian and African countries have no access to contraception or family planning services from any source.

Ecofeminists agree with global feminists that it is important for women to understand how women's interests can diverge as well as converse. When a wealthy U.S. woman seeks to adopt a child, for example, her desire might prompt profiteering middlemen to prey on indigent Asian or African women, desperate to give their yet-to-be-born children a life better than their own. Ecofeminists add another concern to this analysis: In wanting to give her adopted child the best that money can buy, an affluent woman might not realize how her spending habits negatively affect not only less fortunate women and

their families, but also many members of the greater animal community and the environment in general.

Departing from these inclusionary ways of understanding women's oppression, *existentialist* feminists stress how, in the final analysis, all selves are lonely and in fundamental conflict. In The Second Sex, Simone de Beauvoir writes that, from the beginning, man has named himself the Self and woman the Other. If the Other is a threat to the Self, then woman is a threat to man; and if men wish to remain free, they must not only economically, politically, and sexually subordinate women to themselves, but also convince women they deserve no better treatment. Thus, if women are to become true Selves, they must recognize themselves as free and responsible moral agents who possess the capacity to perform excellently in the public as well as the private world.

Like existentialist feminists, *psychoanalytic* and *cultural feminists* seek an explanation of women's oppression in the inner recesses of women's psyche. As they see it, because children are reared almost exclusively by women, boys and girls are psychosocialized in radically different ways. Boys grow up wanting to separate themselves from others and from the values culturally linked to their mothers and sisters. In contrast, girls grow up copying their mothers' behavior and wanting to remain connected to them and others. Moreover, because of the patriarchal cues they receive both in and outside the home, boys and girls-come to think that such "masculine" values as justice and conscientiousness, which they associate with culture and the public world, are more fully *human* than such "feminine" values as caring and kindness, which they associate with nature and the private world.

In the estimation of many *psychoanalytic and cultural* feminists, the solution to this dichotomous, women-demeaning state of affairs rests in some type of dual-parenting arrangement. Were men to spend as much time fathering as women presently spend mothering, and were women to play as active a role in the world of enterprise as men currently do, then children would cease to associate authority, autonomy, and universalism with men and love, dependence, and particularism with women. Rather, they would identify all of these ways of being and thinking as ones that full persons incorporate in their daily lives.

Finally, as *postmodern* feminists see it, all attempts to provide a single explanation for women's oppression not only will fail but should also fail. They *will* fail because there is no one entity, "Woman," upon whom a label may be fixed. Women are individuals, each with a unique story to tell about a particular self. Moreover, any single explanation for "Woman's" oppression *should* fail from a feminist point of view, for it would be yet another instance of so-call "phallogocentric" thought: that is, the kind of "male thinking" that insists on telling as absolute truth *one* and *only* one story about reality. Women must, in the estimation of postmortem feminists reveal their differences to each other so that they can better resist the patriarchal tendency to center, congeal, and cement thought into a rigid "truth" that always was, is, and forever will be.

Because feminist approaches to ethics focus on how power is used to oppress *women* in particular, nonfeminist critics of them have complained that these approaches are "female-biased." Ethics, insist these critics, cannot proceed from a specific standpoint--in this case, from the standpoint of women--and still be regarded as an ethics. Indeed, traditional western ethics has proceeded on the assumption that its values and rules apply to all rational persons equally. Yet, any number of the "Great Philosophers'" moral

theories seem to be based on the *moral experience of men*--usually powerful ones--as opposed to women. For example, Aristotle's ethics reflects the values of Athenian *citizens*: that is, property-owning Greek males. It does not reflect the values of Greek females or of slaves/foreigners--be they male or female. Nevertheless, traditional western ethicists have tried to make the case that, properly interpreted, Aristotle's ethics applies equally well to both women and men, to both non-Greeks and Greeks; and that it would be misguided to *deliberately*--as opposed to *nonreflectively*- construct an ethics that focuses on a specific group of people.

Related to the above controversy are similar controversies about women's history and literature courses, for example. A person developing a feminist approach to ethics could argue, for example, that she is simply doing what Aristotle, Mill, and Kant should have done in the first place--namely, paying as much attention to women's moral experience as men's. In the same way that historians have ignored the stresses, strains, and struggles of the private world of children, church, and kitchen to focus on the economic revolutions, political upheavals, and military conquests of the public world, traditional western ethicists have focused on men's moral interests, issues, and values, failing to notice just how significant and interesting women's moral issues and values are. Therefore, when a proponent of feminist ethics insists on highlighting "women's morality," she may be doing little more than some corrective surgery--adding women's moral experiences to a male-biased ethical tradition sorely in need of them.

However, she may be doing more than this. She may be suggesting that it is not enough for traditional western ethics to incorporate women's interests and issues, and to recognize women as moral agents who must be taken seriously. On the contrary, she may be urging the "Tradition" to rethink all of the ontological and epistemological assumptions upon which it is based; and even to consider the possibility, that far from being sources of human liberation, its principles, rules, regulations, norms, and criteria actually serve to support patterns of domination and subordination that "demoralize" everyone.

If its focus on women-oppressive system and structures is indeed what makes an ethics feminist, as opposed to simply feminine or maternal, then Alison Jaggar's summary of the fourfold function of feminist ethics cannot be improved upon in any significant way. According to Jaggar, all fully feminist approaches to ethics seek to (1) articulate moral critiques of actions and practices that perpetuate women's subordination; (2) prescribe morally justifiable ways of resisting such actions and practices; (3) envision morally desirable alternatives for such actions and practices; and (4) take women's moral experience seriously, though not uncritically (Jaggar, "Feminist Ethics" 1992). Women should not focus on making the world a better place for *everyone* in general; rather, their primary aim should be to make the world a better place for *women* in particular -and perhaps also for other vulnerable people like children, the elderly, the infirm, the disabled, minorities, etc. In Jaggar's estimation, encouraging women with supportive thoughts, kind words, and benign actions is not enough. A feminist approach to ethics entails women resisting and overcoming their continuing oppression under patriarchy.

Lesbian Approaches to Ethics

That feminist approaches to ethics should be so bold as to focus on women is part of what makes them

unique and controversial. In a similar vein, lesbian approaches to ethics dare to focus only on lesbians in what represents a further assault on the Tradition. First, by speaking to lesbians primarily or even exclusively, those developing lesbian approaches to ethics carry "particularity" to what even some feminists believe is a fault. There is concern, for example, that lesbian ethics privileges lesbians' moral concerns over those of heterosexual women. But here the question to ask is if there really is that much difference between an ethics that focuses on lesbians in particular and one that focuses on women in general. In both instances, the purpose of the narrower focus is to identify and overcome structures of domination and subordination.

Second, lesbian ethics threatens the Tradition because thinkers like Mary Daly recommend a transvaluation of values equal to the one Nietzsche offered nineteenth-century western moralists. Nietzsche's disenchantment with western civilization--and its good-naturedness, mediocrity, egalitarianism, softness--led him to redefine and counter prevailing notions of good and bad. Virtue, said Nietzsche, does not consist in what the Jews, Christians, democrats and socialists believe it consists; namely, kindness, humility, and sympathy. Rather it consists in what noble aristocrats, or *übermenschen*, regard as good; namely, assertiveness, aloofness, and pridefulness. What western civilization has come to accept as "good" is in actuality very bad, insisted Nietzsche. Value must be transvalued. What is praised as "virtue" must be exposed as *vice*; and what is condemned as "vice" must be revealed as *virtue*.

Daly is Nietzschean not because she posits two types of morality--a superior female morality and an inferior male morality--but because she insists that when it comes to women, she whom the patriarch calls "evil," is in fact good, whereas she whom the patriarch calls "good" is in fact bad. If a woman is to escape the traps men have laid for her--if she is to assert her power, to be all that she can--she must realize that it is not *good* for her to sacrifice, deny, and deprive herself for the sake of the men and children in her life. What *is* actually good for women, observes Daly, is precisely what patriarchy identifies as *evil* for women; namely, becoming her own person (Daly, Gyn/Ecology, 1978).

Finally and continuing Daly's revolution, Sarah Lucia Hoagland releases in her Lesbian Ethics (1989) the too-long suppressed female freedom to question and choose. Hoagland says women must replace the questions "Am I good?" and "Is this good" with the question "Does this contribute to my self-creation, freedom, and liberation?" Of course, from the perspective of traditional western ethics, Hoagland's question is not the "right" question to ask.

As Hoagland's supporter Marilyn Frye sees it, however, the need to ask the "right" question tends to arise among people who have a vested interest not only in being good but also in making others be good. For example, a white/Christian/middle-class/ heterosexual American bases his conception of himself as a judge, teacher, preacher, director, administrator, manager, leader and in this mode, as an authority, upon his conviction that he is in the right--that he knows what is good for others as well as himself. So long as women continue to accept this "male" conception of moral agency, says Frye, they will have only two choices: (1) to become like men so that they can exert *men's* moral authority over others; or (2) to become female moral authorities who then make it their business to exert *women's* moral authority over others.

That Frye should regard both of these options as unacceptable is not surprising. The first forces women to

negate themselves; and the second sends women down the same moral blind-alley men have supposedly gone. If ethics is about some people not only proclaiming to other people what is "good" for them, but imposing that "good" upon them, then Frye welcomes the criticism that lesbian approaches to ethics are not really about ethics. Only those who have a vested interest in the status quo, in the powerful remaining powerful, require certitude about their righteousness and their warrant to "direct" and "administer" everything. But because lesbians are some of society's least powerful members, says Frye, they have no way to impose their conception of the good on anyone but themselves nor do they have any desire to do so (Frye, "A Response to Lesbian Ethics: Why Ethics?", 1991).

Claiming the particularity rather than universality of their conception of the good, lesbian ethicists contrast their self-created values with the Tradition's other-imposed values. They imply that insofar as lesbians are concerned, the act of choosing, in and of itself, makes what is chosen somehow "good." More than any other feature of lesbian ethics, it is this one that provokes comment from its nonfeminist critics. These critics ask thinkers like Frye and Hoagland if it makes no moral difference to them what a lesbian chooses, provided that she *freely* choose it.

To this query Hoagland has a response. She notes that so many limitations and boundaries have been imposed on lesbian choice that perhaps for now choice *is* of more moral importance to lesbians than the things chosen. Still, Hoagland does not mean to insist there are no limits on lesbian choice. At one point in her analysis of what constitutes moral agency and interaction, Hoagland observes that in choosing for herself, a lesbian chooses for other lesbians, who in turn choose for her. Lesbians do not weave value in isolation from each other; they weave value together. Ethics is not an individualistic quest; moral value does not emerge from somewhere deep within one's self or from far outside of one's self. On the contrary, moral value--that is, meaning--emerges from what Hoagland terms "lesbian context," or "an energy field capable of resisting oppression." A lesbian approach to ethics is about lesbians becoming the kind of human beings who refuse to participate in anything other than egalitarian relationships (Hoagland, Lesbian Ethics, 1989)..

Insofar as relationships of domination and subordination are a very bad thing indeed, what heterosexual women and men can learn from a lesbian approach to ethics, then, is what Hoagland and other lesbian ethicists--Maria Lugones in particular--term "playfulness;" that is, "the ability to travel in and out of each other's worlds" (Lugones, "Playfulness, ‘World’-travelling, and Loving Perception," 1987). In fact, Hoagland believes that playfulness is the essence of a lesbian approach to ethics--a welcome relief, to what she perceives as the deadly and deadening seriousness of traditional western approaches to ethics. An emphasis on playfulness--on adventure, curiosity, desire--enables lesbians to create moral meanings and values for lesbians only, leaving it to nonlesbians to create their own moral meanings and values.

Conclusion

Although feminine, maternal, feminist, and lesbian approaches to ethics are all women-centered, they do not impose a single normative standard on women. Rather they offer to women multiple standards that validate women's different moral experiences in ways that points to the weaknesses as well as the

strengths of the values and virtues culture has traditionally labeled "feminine." In addition, they suggest to women several paths, all of which lead toward the one goal that is essential to the project of any women-centered ethics; namely, the elimination of gender inequality.

Although feminists' different interpretations of what constitutes a voluntary and intentional choice, an illegitimate or legitimate exercise of control, and a healthy or a pathological relationship reassure the intellectual and moral community that, after all, feminism is not a monolithic ideology that prescribes one and only one way for *all* women to be, this variety of thought is also the occasion of considerable political fragmentation among feminists. Asked to come to the policy table to express *the* feminist perspective on a moral issue, all that an honest feminist ethicist can say is that there is *no* such perspective. Yet, if feminists have no clear, cogent, and unified position on a key moral issue, then a perspective less appealing to women may fill the gap. Although it is crucial for feminist ethicists to emphasize, for example, how a policy that benefits one group of women might at the same time harm another group of women, it is probably a mistake for feminist ethicists to leave the policy table without suggesting policies that are able to serve the *most important* interests of the *widest* range of women. For this reason, many feminist ethicists believe that, over and beyond their commitment to eliminating gender inequality, feminists need to develop a mutually-agreeable methodology that will permit them to achieve a consensus position on many, if not all, the moral issues related to women. Feminist ethicists have a moral duty first to listen to each others' differing points of view, and then to develop a theory and practice that, despite their shortcomings, will nevertheless help inch as many women as possible towards the goal of gender equality with men.

Feminist Epistemology and Philosophy of Science

Feminist epistemology and philosophy of science studies the ways in which gender does and ought to influence our conceptions of knowledge, the knowing subject, and practices of inquiry and justification. It identifies ways in which dominant conceptions and practices of knowledge attribution, acquisition, and justification systematically disadvantage women and other subordinated groups, and strives to reform these conceptions and practices so that they serve the interests of these groups. Various practitioners of feminist epistemology and philosophy of science argue that dominant knowledge practices disadvantage women by (1) excluding them from inquiry, (2) denying them epistemic authority, (3) denigrating their "feminine" cognitive styles and modes of knowledge, (4) producing theories of women that represent them as inferior, deviant, or significant only in the ways they serve male interests, (5) producing theories of social phenomena that render women's activities and interests, or gendered power relations, invisible, and (6) producing knowledge (science and technology) that is not useful for people in subordinate positions, or that reinforces gender and other social hierarchies. Feminist epistemologists trace these failures to flawed conceptions of knowledge, knowers, objectivity, and scientific methodology. They offer diverse accounts of how to overcome these failures. They also aim to (1) explain why the entry of women and feminist scholars into different academic disciplines, especially in biology and the social sciences, has generated new questions, theories, and methods, (2) show how gender has played a causal role in these transformations, and (3) defend these changes as cognitive, not just social, advances.

The central concept of feminist epistemology is that of a situated knower, and hence of situated knowledge: knowledge that reflects the particular perspectives of the subject. Feminist philosophers are interested in how gender situates knowing subjects. They have articulated three main approaches to this question: feminist standpoint theory, feminist postmodernism, and feminist empiricism. Different conceptions of how gender situates knowers also inform feminist approaches to the central problems of the field: grounding feminist criticisms of science and feminist science, defining the proper roles of social and political values in inquiry, evaluating ideals of objectivity and rationality, and reforming structures of epistemic authority.

Situated Knowers

Feminist epistemology conceives of knowers as situated in particular relations to what is known and to other knowers. What is known, and the way that it is known, thereby reflects the situation or perspective of the knower. Here we are concerned with *claims* to know, temporarily bracketing the question of which claims are true or warranted.

Situated knowledge in general. Consider how people may understand the same object in different ways that reflect the distinct relations in which they stand to it.

Embodiment. People experience the world by using their bodies, which have different constitutions and are differently located in space and time. In virtue of their different physical locations, observers who stand in front of an object have different information about it than observers who have a distant but bird's eye view of it.

First-person vs. third-person knowledge. People have first-personal access to some of their own bodily and mental states, yielding direct knowledge of phenomenological facts about what it is like for them to be in these states. Third parties may know these states only by interpreting external symptoms, imaginative projection, or obtaining their testimony. People also have knowledge *de se* about themselves, expressed in the form "*I* am F *here, now*." This is distinct in character and inferential role from propositional knowledge having the same content, which does not use indexicals.

Emotions, attitudes, interests, and values. People often represent objects in relation to their emotions, attitudes and interests. A thief represents a lock as a frustrating obstacle while its owner represents the lock as a comforting source of security.

Personal knowledge of others. People have different knowledge of others, in virtue of their different personal relationships to them. Such knowledge is often tacit, incompletely articulated, and intuitive. Like the knowledge it takes to get a joke, it is more an interpretive skill in making sense of a person than a set of propositions. (The German language usefully marks this as the distinction between *Erkenntnis*

and *Wissenschaft*.) Because people behave differently toward others, and others interpret their behavior differently, depending on their personal relationships, what others know of them depends on these relationships. *Know-how.* People have different skills, which may also be a source of different propositional knowledge. An expert dog handler knows how to elicit more interesting behavior from an a dog than a novice does. Such know-how expresses a more sophisticated understanding of dogs on the part of the expert, and also generates new phenomena about dogs for investigation.

Cognitive Styles. People have different styles of investigation and representation. What looks like one phenomenon to a lumper may look like three to a splitter. *Background beliefs and worldviews.* People form different beliefs about an object, in virtue of different background beliefs. In virtue of the different background beliefs against which they interpret a patient's symptoms, a patient may think he is having a heart attack while his doctor believes he just has heartburn. Differences in global metaphysical or political worldviews (naturalism, theism, liberalism, marxism) may also generate different beliefs about particulars on a more comprehensive scale.

Relations to other inquirers. People may stand in different epistemic relations to other inquirers -- for example, as informants, interlocutors, students -- which affects their access to relevant information and their ability to convey their beliefs to others.

These kinds of situatedness affect knowledge in several ways. They influence knowers' access to information and the terms in which they represent what they know. They bear on the form of their knowledge (articulate/implicit, formal/informal, by acquaintance or description, and so forth). They affect their attitudes toward their beliefs (certainty/doubt, dogmatic/open to revision), their standards of justification (relative weights they give to different epistemic values such as predictive power and consilience, amount, sources, and kinds of evidence they require before they accept a claim, etc.), and the authority with which they lay claim to their beliefs and can offer them to others. Finally, they affect knowers' assessment of which claims are significant or important.

Social situation. Many of these ways in which knowers' physical and psychological relations to the world affects what and how they know are familiar and extensively studied by cognitive psychology, naturalized epistemology, and philosophy of science. Feminist epistemology takes such studies a further step by considering how the social location of the knower affects what and how she knows. It can thus be seen as a branch of social epistemology. An individual's social locations consists of her ascribed social identities (gender, race, sexual orientation, ethnicity, caste, kinship status, etc.) and social roles and relationships (occupation, political party membership, etc.). Partly in virtue of their different ascribed identities, individuals occupy different social roles that accord them different powers, duties, and role-given goals and interests. They are subject to different norms that prescribe different virtues, habits, emotions, and skills that are thought to be appropriate for these roles. They also acquire different subjective identities. Subjective identification with one's social groups can take several forms. One may simply know oneself to have certain ascribed identities. One may accept or endorse these identities, actively affirming the norms and roles associated with them. Or one may regard one's social identities as oppressive (if, say, one's identity is cast by society as evil, contemptable, or disgusting), yet see one's fate as tied with the groups with which one is identified, and commit oneself to collective action with other

members of those groups to overcome that oppression.

Gender as a mode of social situation. Most feminist theorists distinguish between sex and gender. Sex comprises the biological differences between males and females. Gender is what societies make of sexual differences: the different roles, norms, and meanings they assign to men and women and the things associated with them on account of their real or imagined sexual characteristics. Gender thus has several dimensions (Haslanger 2000).

Gender roles. Men and women are assigned to distinct social roles. For example, most societies reserve political and military offices mostly for men, and assign women most childrearing responsibilities.

Gender norms. Men and women are expected to comply with different norms of behavior and bodily comportment. For example, men are expected to be assertive and athletic; women, deferential and modest. Gender norms are tailored to gender roles: men and women are expected to conform to those norms that make them fit for their gender roles (whether or not they actually occupy those roles).

Gendered traits and virtues. Psychological traits are considered "masculine" and "feminine" if they dispose their bearers to comply with the gender norms assigned to men and women, respectively. "Masculine" traits are therefore regarded as virtues in men and (often) vices in women, while "feminine" traits are regarded as vices in men and virtues in women.

Gendered performance/behavior. Many feminist theorists, often influenced by postmodernism, have come to stress the contextual and performative aspects of gender (West and Zimmerman 1987; Butler 1990). Rather than viewing masculinity and femininity as fixed traits, expressed in every social context, these theorists represent human beings as more flexible and disposed to enact both "masculine" and "feminine" behaviors in different contexts. The man who avoids tenderly comforting a crying baby in the presence of women may do so when alone. Rather than viewing masculinity and femininity as manifested only in behavior within fixed, distinct gender roles, they can be seen as contrasting styles of performance in almost any role. Female body builders strive to show off their muscles in a "feminine" way.

Gender identity. A person's ascribed gender identity -- how others identify him or her -- may not match his or her subjective gender identity -- the sense that one is "really" a man or a woman. Subjective gender identity includes all of the ways one might understand oneself to be a man or a woman. One could identify with any subset of gender norms, roles, and traits ascribed to the gender of which one sees oneself as a member, while repudiating others. One could even repudiate them all, but still identify oneself as a man or a women in terms of what one sees as distinct roles men and women ought to play in bringing about a just future (one that may or may not include gender distinctions). One could, as many feminists do, understand one's gender identity as a predicament shared by all with the same ascribed identity, and thus as a basis for collective action to change the very basis of one's gender identity. One could embrace an "androcentric" identity, including both "feminine" and "masculine" roles, norms, and traits, decline to view oneself in gender polarized terms at all, or play with gender identities in a postmodernist spirit.

Gender symbolism. Animals and inanimate objects may be placed in a gendered field of representation through conventional association, imaginative projection, and metaphorical thinking. Thus, the garage is regarded as "male" space, the kitchen, "female"; male deer are said to have "harems"; pears are seen as "womanly", assault rifles as "manly."

Gendered knowledge. By bringing together the general account of situated knowledge with the account of gender as a kind of social situation, we can now generate a catalogue of ways in which what people know, or think they know, can be influenced by their own gender (roles, norms, traits, peformance, identities), other people's genders, or by ideas about gender (symbolism). Each mode of gendered knowledge raises new questionsfor epistemology.

The phenomenology of gendered bodies. People's bodies are not just differently sexed; they are differently gendered. Early child socialization trains boys' and girls' bodies to different norms of bodily comportment. In the U.S., these norms stress physical freedom, aggressive play, large motor skills, informal and relaxed posture, and indifference to clothing, neatness and appearance in boys; physical constraint, subdued play, small motor skills, formal and modest posture, and self-consciousness about clothing, neatness and appearance for girls. Once internalized, such norms profoundly affect the phenomenology of embodiment. They inform men's and women's distinct first-personal knowledge of what it is like to inhabit a body, to express capacities unique to one sex or another (e.g., breast feeding), and to have experiences that are manifested through different body parts in differently sexed bodies (e.g., orgasm). They also cause men's and women's experiences of gendered behaviors that both can peform to differ -- in comfort, fluidity, feelings of "naturalness" or novelty, self-consciousness, confidence, awkwardness, shame, and so forth. One question these facts raise for feminist epistemology is to what extent dominant models of the world, especially of the relation between minds and bodies, have seemed compelling because they conform to a male or masculine phenomenlogy (Bordo 1987; Young 1990).

Gendered first-personal knowledge de se. It is one thing to know what sexual harassment is, and how to identify it in a case described in third-personal terms. It is another to come to the recognition "*I* have been sexually harassed." Many women who are able to see that women in general are disadvantaged have difficulty recognizing themselves as sharing women's predicament (Clayton and Crosby 1992). The problems of *de se* knowledge are particularly pressing for feminist theory, because it is committed to theorizing in ways that women can use to improve their lives. This entails that women be able to recognize themselves and their lives in feminist accounts of women's predicament. Feminist epistemology is therefore particularly concerned with investigating the conditions of feminist self-understanding and the social settings in which it may arise -- feminist consciousness-raising sessions, women's studies classes, and so forth (MacKinnon 1989).

Gendered emotions, attitudes, interests, and values. Feminist theory defines a representation as *androcentric* if it depicts the world in relation to male or masculine interests, emotions, attitudes or values. A "male" interest is an interest a man has, in virtue of the goals given to him by social roles that are designated as especially appropriate for men to occupy, or in virtue of his subjective gender identity. A "masculine" interest is an interest a man has in virtue of attitudes or psychological dispositions that are

thought specifically appropriate to men. Such attitudes and interests structure the cognition of those who have them. For example, a representational scheme that classifies women as either "babes," "dogs," "whores," or (grand)mothers reflects the androcentric attitudes, interests, and values of single heterosexual adolescent men who view women in terms of their fantasized eligibility for sexual intercourse with them. A representation is *gynocentric* if it depicts the world in relation to female or feminine interests, emotions, attitudes or values. When a man is described as an "eligible bachelor," this reflects the gynocentric perspective of a heterosexual, single woman interested in marriage. An interest, emotion, attitude, or value might be symbolically gendered even if men and women do not manifest it differently. For example the ethics of care represents moral problems in terms of symbolically feminine values -- values culturally associated with women's gender roles (Gilligan 1982). It thus can qualify as a symbolically gynocentric perspective, even if men and women do not differ in their propensity to represent moral problems in its terms, and are equally able to act accordingly. From a performative perspective, this shows that men can behave in "feminine" ways, too. Feminist epistemology raises numerous questions about these phenomena. Can situated emotional responses to things be a valid source of knowledge about them (Diamond 1991, Jaggar 1989, Keller 1983)? Do dominant practices and conceptions of science and scientific method reflect an androcentric perspective, or a perspective that reflects other dominant positions, as of race and colonial rule (Merchant 1980; Harding 1986, 1991, 1993, 1998)? Do mainstream philosophical conceptions of objectivity, knowledge, and reason reflect an androcentric perspective (Bordo 1987; Code 1991; Flax 1983; Rooney 1991)? How would the conceptual frameworks of particular sciences change if they reflected women's interests (Anderson 1995b, Waring 1990)?

Knowledge of others in gendered relationships. Gender norms differentially structure the social spaces to which men and women are admitted, as well as the presentation of self to others. As performative theories of gender stress, men manifest their male identity, and women their female identity, differently alone than in mixed company, and differently in these settings than in gender-segregated contexts. Male and female inquirers therefore have access to different information about others. Male and female ethnographers may be admitted to different social spaces. Even when admitted to the same social spaces, their presence has different effects on those being observed, because they do not stand in the same social relationships to their subjects. Physical objects do not behave differently depending on whether a man or a woman is observing them. But human beings do behave differently according to their beliefs about the gender of who is observing them. Research that elicits information about others through personal contact between the researchers and the research subjects therefore raises the question of how findings might be influenced by the gendered relations between researchers and subjects, and whether gender-inclusive research teams are in a better position to detect this. Ethnography, which derives propositional knowledge of others from personal knowledge of native informants in long-term, often intimate relationships, raises these issues most acutely (Bell et al 1993; Leacocke 1981). Similar issues arise in survey research, clinical research, and human experimentation (Sherif 1987).

Gendered skills. Some skills are labelled masculine or feminine because men and women need them specifically to perform their respective gender roles, and they are not generically useful for almost any role (as walking, talking, and seeing are). It takes a particular knowledge of small children to know how to comfort them, a particular knowledge of soldiers to know how to whip up their morale. Although men

and women alike may acquire and exercise these skills, they are considered the peculiar responsibility of one or the other gender. Men and women may therefore have differential access to such skill-based knowledge. To the extent that the skill is perceived by the agent as the proper province of the "other" gender, he or she may have a difficult time seeing himself or herself perform it confidently and fluidly, and this inability to self-identify with the task can impair performance. The feedback effects of the phenomenology of gendered embodiment and *de se* knowledge of one's own subjective gender identity can therefore influence the exercise of gendered skills. To the extent that a skill is perceived by others as the proper province of one gender, others may grant or withhold acknowledgment of an agent's expertise. If the successful exercise of the skill requires that others be willing to accept it as a competent performance -- as in the cases of comforting children or raising soldiers' morale -- others' gender-based readiness or refusal to grant expertise to an agent in exercising that skill can be a self-fulfilling prophecy. These phenomena raise various questions for epistemology. Does the "masculine" symbolism of certain scientific skills, such as of assuming an "objective" stance toward nature, interfere with the integration of women into science? Do actually or symbolically "feminine" skills aid the acquisition of scientific knowledge (Keller 1983, 1985a; Rose 1987; Smith 1974)?

Gendered cognitive styles. Some theorists believe that men and women have different cognitive styles (Belenky et al 1986; Gilligan 1982). Whether or not this is true, cognitive styles are gender symbolized (Rooney 1991). Deductive, analytic, atomistic, acontextual, and quantitative cognitive styles are labelled "masculine," while intuitive, synthetic, holistic, contextual and qualitative cognitive styles are labelled "feminine." Such associations are not wholly arbitrary, the way blue is gendered male and pink, female. For example, it is seen as masculine to make one's point by means of argument, feminine to make one's point by means of narrative. Argument is commonly cast as an adversarial mode of discourse, in which one side claims vindication by vanquishing the opposition. Such pursuit of dominance follows the competitive pattern of male gender roles in combat, athletics, and business. Narrative is a seductive mode of discourse, persuading by an enticing invitation to take up the perspective of the narrator, which excites one's imagination and feeling. Its operations are more like love than war, and thereby follows a mode of persuasion thought more suitable for women. These phenomena raise numerous epistemological questions: does the quest for "masculine" prestige by using "masculine" methods distort practices of knowledge acquisition (Addelson 1983; Moulton, 1983)? Are some kinds of sound research unfairly ignored because of their association with "feminine" cognitive styles (Keller 1983, 1985b)? Do "feminine" cognitive styles yield knowledge that is inaccessible or harder to achieve by "masculine" means (Duran 1991, Rose 1987, Smith 1974)?

Gendered background beliefs and worldviews. We have seen above how men and women have access to different phenomenological knowledge, *de se* knowledge, know-how, and personal knowledge of others, in virtue of their gender. They also tend to represent the world in different terms, in virtue of their gendered interests, attitudes, emotions and values, and perhaps also (although this is a matter of controversy among feminist theorists) in virtue of different cognitive styles. These differences create different background webs of belief against which information to which men and women have in principle equal access may be processed. Representational schemes that are functional for different gender roles and gendered attitudes make different kinds of information salient. In traditional domestic settings, women tend to notice dirt that men don't. This is not because women have a specially sensitive

sensory apparatus. It is because they have a role which designates the females of the household as the ones who have to clean up. Male surgeons have no difficulty maintaining much higher degrees of vigilance about contamination in an operating room than would ever be warranted in housecleaning. Besides making different kinds of information salient to men and women, their different background knowledge may lead them to interpret commonly accessed information differently. A man might read a woman's demure smile as a coy come-on, where another woman may interpret it as her polite and defensive reaction to unwanted attention from him. Such differences can spring from differential access to phenomenological knowledge. The male and female observers imaginatively project themselves into her situation, inferring her feelings from the feelings they think underlie her body language. Because men's and women's phenomenologies of embodiment are different -- most men are not in the habit of smiling as a defense against unwanted attention from women -- the man may narcissistically imagine the smile as relaxed and spontaneous, whereas the woman may suspect it is forced. Here are a few epistemological questions raised by these phenomena. Are there epistemic obtacles to men's ability to know when they are raping or sexually harassing women, or to legal institutions recognizing this, insofar as they confine their thinking within a "masculine" perspective (MacKinnon 1989)? More generally, do the unexamined sexist or androcentric background beliefs of scientists cause them to generate sexist theories about women, despite their adherence to ostensibly objective scientific methods (Harding 1986; Harding and O'Barr, 1987; Hubbard 1990)? More generally still, how might the social practices of science be organized so that variations in background beliefs of inquirers function as a resource rather than an obstacle to scientific success (Longino 1990; Solomon 1994)?

Relations to other inquirers. Gender differences in knowledge and background beliefs can be reduced if men and women participate in inquiry together. Each gender can take on testimony what the other can acquire through direct experience. Each may also learn how to exercise imaginative projection more effectively, and to take up the perspective of the other gender. However, gender norms influence the terms on which men and women communicate (Kalbfleisch 1995). In many contexts, women are not allowed to speak or even show up, or their questions, comments, and challenges are ignored, interrupted, and systematically distorted, or they aren't accepted as experts. Gendered norms of conversational interaction and epistemic authority thus influence the ability of knowledge practices to incorporate the knowledge and experience of men and women into their processes of discovery and justification. Feminist epistemologists are therefore interested in exploring how gender norms distort the dissemination of testimony and relations of cognitive authority among inquirers (Addelson 1983; Code 1991) and how the social relations of inquirers could be reformed, especially with regard to the allocation of epistemic authority, so as to enable more successful practices of inquiry (Longino 1990; Nelson 1990, 1993).

Problems of and Approaches to Gendered Situated Knowledge. Mainstream epistemology takes as paradigms of knowledge simple propositional knowledge about matters in principle equally accessible to anyone with basic cognitive and sensory apparatus: "2 + 2=4"; "grass is green"; "water quenches thirst." Feminist epistemology does not claim that such knowledge is gendered. But examination of such examples is not particularly helpful for answering the epistemological problems that arise specifically in feminist theory and practice. What is it to know that I am a woman? What is it like to be sexually objectified? Why is it that men and women so often have dramatically divergent understandings of what happened in their sexual encounters? How can we arrange scientific practices so that science and

technology serve women's interests? These kinds of questions make other kinds of knowledge salient for feminist epistemology: phenomenological knowledge, *de se* knowledge, knowledge of persons, know-how, moral knowledge, knowledge informed by emotions, attitudes, and interests. These kinds of knowledge are often gendered, and they can influence the propositional claims people are disposed to form and accept. This has critical implications for mainstream epistemological conceptions of knowledge, insofar as the latter are based on false generalizations drawing only from examples of ungendered knowledge.

Feminist epistemologists stress the situatedness or perspective-relativity of much knowledge. They do not thereby embrace epistemological relativism. To regard some knowledge claim or form of understanding as situated in a perspective is not to claim that the perspective yields true beliefs or satisfactory understandings (not even "for" those taking up the perspective). It is not to claim that perspectives can only be judged in their own terms, nor that no perspectives are better than others, nor that one cannot take a more objective view of the phenomena than that taken up in one or another perspective. It is not to claim that all knowledge necessarily reflects some peculiar non-universalizable relation of a subset of knowers to the object of knowledge. What attention to situated knowledge does do is enable questions to be raised and addressed that are difficult even to frame in epistemologies that simply assume that gender, and the social situation of the knower more generally, is irrelevant to knowledge. How are the knowledge claims generated by gendered perspectives related to one another? Can men take up a gynocentric perspective, and women, an androcentric perspective? Or are there epistemological barriers to such perspective crossing? Are certain perspectives epistemically privileged? Is there any way to construct a more objective perspective out of differently gendered perspectives? What is the relation of an objective perspective, if one is possible, to gendered perspectives? What would be the point of achieving such a perspective? Would the achievement of such an objective perspective make possible or desirable the elimination of gendered perspectives? Feminist epistemology does not rule out in advance the possibility or desirability of objective knowledge. It does raise new questions about objectivity.

Feminist epistemologists have developed their approaches to the situatedness of knowledge within three broad epistemological traditions: standpoint theory, postmodernism, and empiricism. Standpoint theory identifies one particular social situation as epistemically privileged. Postmodernism rejects claims of epistemic privilege, emphasizing instead the contingency and instability of the social identity of knowers, and consequently of their representations. Empiricism seeks standards, within a naturalized framework, for differentiating the circumstances in which situatedness generates error and in which it constitutes a resource that can be harnessed to advance knowledge. It advances a conception of objectivity constituted by critical and cooperative relations among a plurality of differently situated inquirers.

Feminist Standpoint Theory

Standpoint Epistemology in General. Standpoint theories claim to represent the world from a particular socially situated perspective that can lay a claim to epistemic privilege or authority. A complete standpoint theory must specify (i) the *social location* of the privileged perspective, (ii) the *scope* of its privilege: what questions or subject matters it can claim a privilege over, (iii) the *aspect* of the social

location that generates superior knowledge: for example, social role, or subjective identity; (iv) the *ground* of its privilege: what it is about that aspect that justifies a claim to privilege; (v) the *type* of epistemic superiority it claims: for example, greater accuracy, or greater ability to represent fundamental truths; (vi) the *other perspectives* relative to which it claims epistemic superiority and (vii) modes of access to that perspective: is occupying the social location necessary or sufficient for getting access to the perspective? Many claims to epistemic privilege on behalf of particular perspectives with respect to certain questions are commonplace and uncontroversial. Auto mechanics are generally in a better position than auto consumers to know what is wrong with their cars. Practical experience in fulfilling the social role of the mechanic grounds the mechanic's epistemic privilege, which lays a claim to greater reliability than the judgments of auto consumers.

Standpoint theories become controversial when they claim epistemic privilege over socially and politically contested topics on behalf of the perspectives of systematically disadvantaged social groups, relative to the perspectives of the groups that dominate them. The scope of the claimed privilege includes the character, causes, and consequences of the social inequalities that define the groups in question. This type of standpoint theory *classically* claims three types of epistemic privilege over the standpoint of dominant groups: First, it claims to offer deep over surface knowledge of society: the standpoint of the disadvantaged reveals the fundamental regularities that drive the phenomena in question, whereas the standpoint of the privileged captures only surface regularities. Second, in virtue of this, it claims to offer superior knowledge of the modality of surface regularities, and thus superior knowledge of human potentialities. Where the standpoint of the privileged tends to represent existing social inequalities as natural and necessary, the standpoint of the disadvantaged correctly represents them as socially contingent, and shows how they could be overcome. Third, it claims to offer a representation of the social world in relation to universal human interests. By contrast, the standpoint of the privileged represents social phemonena only in relation to the interests of the privileged class, but ideologically misrepresents these interests as coinciding with universal human interests.

Marxist Standpoint Theory. Marxism offers the classic model of a standpoint theory, claiming an epistemic privilege over fundamental questions of economics, sociology, and history on behalf of the standpoint of the proletariat (Marx 1964, Lukács 1971). Workers do not have this standpoint to begin with. They attain it by gaining collective consciousness of their role in the capitalist system and in history. Several aspects of workers' social situation enable them to attain an epistemically privileged perspective on society. Workers are oppressed, central to the capitalist mode of production, endowed with a cognitive style based on their practical productive material interaction with nature, and collectively self-conscious agents of a potentially universal class. Oppression gives them an objective interest in the truth about whose interests really get served by the capitalist system. Centrality gives them experiential access to the fundamental relations of capitalist production. Because, under capitalism, the standing of all other classes is defined in relation to them, in coming to know themselves and their class position, workers come to know their society as a totality (Lukács 1971). Practical productive interaction with the world is the fundamental mode by which people come to know it, in a materialist epistemology. It leads workers to represent their world in terms of use values, whereas capitalists represent it in terms of exchange values. The workers' representation is more fundamental, because the basic laws of economics and history are expressed in terms of the struggle over the appropriation of surplus (use-) value, not in terms

of superficial money (exchange) values. The necessary and transhistorical character of this practical, instrumental mode of knowing also gives it an objective validity for all societies, which must come to grips with accounting for surplus value in terms of ultimate use-values. Universality -- the workers' standing as the agents for the future universal class they will become under communism (where everyone has the same class status, standing in a common relation to the means of production as both workers and collective rulers over the surplus) -- entails that workers represent the social world in relation to universal human interests, rather than in relation to class-specific interests (as is true of capitalist perspectives). This gives their representations of society greater objectivity than capitalist representations. Finally, the collective self-consciousness of the workers has, as all successful intentional action does, the character of a self-fulfilling prophecy. Workers' collective insight into their common predicament and the need to overcome it through collective revolutionary action generates a self-understanding which, when acted upon, gets realized. Workers become the universal class, the primary agent of history, by acting on that self-understanding. The epistemic privilege of the standpoint of the proletariat, therefore, is also grounded in the epistemic privilege that autonomous agents have over what they are doing.

Grounds of Feminist Standpoint Theory. Feminist standpoint theory claims an epistemic privilege over the character of gender relations, and of social and psychological phenomena in which gender is implicated, on behalf of the standpoint of women. The privilege is relative to theories that justify patriarchy or reflect sexist assumptions. Various feminist standpoint theories ground the claim to epistemic privilege in different features of women's social situation. Each can be seen as drawing an analogy with one or more strands of Marxist epistemology.

Centrality. According to marxist feminists, such as Hartsock (1987) and Rose (1987) women are central to the system of reproduction -- of socializing children and caring for bodies -- as workers are central to the system of commodity production. Because women are in charge of tending to the needs of everyone else in the household, they are in a better position than men to see how patriarchy fails to meet people's needs. Men, in virtue of their dominant position, have the privilege of ignoring how their actions undermine the interests of subordinates. The epistemic privilege of women therefore rests on the fact that women as a class have superior access to information about whose needs get better served under patriarchy.

Collective self-consciousness. According to MacKinnon (1999) male dominance is based on sexual objectification, a process involving epistemic mystification. In objectification, dominant groups project their desires onto subordinate groups and, in virtue of their power, make subordinate groups conform to the way dominants want them to be. It represents as given, natural, and necessary the group differences that are caused by dominant group desires. Gender is the mode of objectification constituted by erotic desire, the eroticization of domination. Men constitute women as women by representing their natures as essentially sexually subordinate to men and treating them accordingly. Women can unmask these ideological misrepresentations by achieving and acting on a shared understanding of themselves as women -- that is, as a social group unjustly constituted by sexual objectification. Women act collectively on this shared understanding in resisting the sexist representations made of them, through campaigns against sexual harassment, pornography, restrictions on reproductive freedom, and so forth. Through these feminist actions, in which women refuse to act as sexual objects, women show that representations

of women as sexual objects are not natural or necessary. Their privileged knowledge is agent self-knowledge, made true by being put into action.

Cognitive style. Many versions of standpoint theory (including Flax 1983, Hartsock 1987, Rose 1987, and Smith 1974) accept feminist object relations theory, which explains the development of stereotypical feminine and masculine traits in terms of the different problems of identity-formation faced by male and female children who are raised by female caregivers (Chodorow 1978). Object relations theory postulates that male children form their distinctive masculine identities by separating themselves from their mothers, a task that psychologically involves an anxious rejection of the feminine and a continuous need to maintain distance and boundaries by controlling and denigrating the feminine. Female children gain a sense of their gender identity through identification with their mothers, and so are more comfortable with a blurring of boundaries between self and other. The development of gender identities leads males and females to acquire distinctively masculine and feminine cognitive styles. The masculine cognitive style is abstract, theoretical, disembodied, emotionally detached, analytical, deductive, quantitative, atomistic, and oriented toward values of control or domination. The feminine cognitive style is concrete, practical, embodied, emotionally engaged, synthetic, intuitive, qualitative, relational, and oriented toward values of care. These cognitive styles are reinforced through the distinctive types of labor assigned to men and women -- men having a near monopoly on the theoretical sciences, warmaking, and on positions of political and economic power calling for detachment and control; and women being assigned to hands-on emotional care for others. The feminine cognitive style is said to be epistemically superior because it overcomes the dichtomy between the subject and object of knowing and because an ethics of care is superior to an ethics of domination. Ways of knowing informed by the motive of caring for everyone's needs will produce more valuable representations than ways of knowing informed by the interests of the dominant (Hartsock 1987). They will produce representations of the world in relation to universal human interests, rather than in terms of the interests of dominant classes, ideologically misrepresented as universal interests. To institutionalize the feminine way of knowing, however, would require overcoming the division of mental, manual, and caring labor that characterizes capitalist patriarchy (Rose 1987).

Oppression. Women are oppressed, and therefore have an interest in representing social phenomena in ways that reveal rather than mask this truth. They also have direct experience of their oppression, unlike men, whose privilege enables them to ignore how their actions affect women as a class. The logic of an epistemology that grounds epistemic privilege in oppression is to identify the multiply oppressed as multiply epistemically privileged. Within feminist theory, this logic has led to the development of black feminist epistemology. Collins (1990) grounds black feminist epistemology in black women's personal experiences of racism and sexism, and in cognitive styles associated with black women. She uses this epistemology to supply black women with self-representations that enable them to resist the demeaning racist and sexist images of black women in the wider world, and to take pride in their identities. The epistemic privilege of the oppressed is sometimes cast, following W.E.B. DuBois, in terms of "bifurcated consciousness": the ability to see things both from the perspective of the dominant and from the perspective of the oppressed, and therefore to comparatively evaluate both perspectives (Harding 1991, Smith 1974, Collins 1990). Black women are "outsiders within," having enough personal experience as insiders to know their social order, but enough critical distance to empower critique.

Access to the Feminist Standpoint. Every standpoint theory must offer an account of how one gains access to its situated knowledge. This depends on whether membership in the group whose perspective is privileged is defined objectively, in terms of one's position in a social structure, or subjectively, in terms of one's subjective identification as a member of the group. When group membership is defined objectively, it is neither necessary nor sufficient for gaining access to the privileged perspective. It is not sufficient, because one might be unaware of the fact or objective significance of being a member of the group. Members become aware of their objective group identity only by achieving a shared understanding of their predicament with other group members. This is the function of consciousness-raising groups in feminist practice (MacKinnon 1999). It is not necessary, because when a group is defined objectively, the facts that constitute the group as such and its interests are publicly accessible, so anyone can theorize phenomena in relation to the interests of that group. Thus, Marx theorized from the standpoint of the proletariat, even though he was not a worker. However, to the extent that the ground of epistemic privilege lies in the self-knowledge of autonomous agents, only those who participate in that agency can have first-personal agent knowledge. At this point, the site of epistemic privilege shifts from the group as defined objectively to the group defining itself as a collective political agent. The privileged standpoint is not that of women, but of feminists. Men can participate in the feminist movement, too. But they cannot assume a dominant role in defining (hence knowing) the aims of the feminist movement without defeating that movement, given that a constitutive aim of feminism is overcoming male dominance. When group membership is defined subjectively, then membership in the group is both necessary and sufficient to gain access to the perspective of the group. If subjectively identifying as a woman is necessary and sufficient to have a feminine cognitive style, as object-relations theory postulates, then all and only self-identified woman have access to the epistemically privileged standpoint. Similarly, Collins' (1990) version of black feminist epistemology rests on identity politics.

Goals of Feminist Standpoint Theory. Feminist standpoint theory is a type of *critical theory*, as this term was understood by the Frankfurt school of critical social theorists, from Adorno to Habermas. Critical theories aim to empower the oppressed to improve their situation. They therefore incorporate pragmatic constraints on theories of the social world. To serve their critical aim, social theories must (a) represent the social world in relation to the interests of the oppressed -- i.e., those who are the subjects of study; (b) supply an account of that world which is accessible to the subjects of study, which enables them to understand their problems; and (c) supply an account of the world which is usable by the subjects to study to improve their condition. Critical theory is theory of, by, and for the subjects of study. These pragmatic features of critical theory raise the possibility that claims of superiority for particular theories might be based more on pragmatic than epistemological virtues (Harding 1991, Hartsock 1996). Even if a particular feminist theory cannot make good on the claim that it has *privileged* access to reality, it may offer true representations that are more *useful* to women than other truthful representations.

Criticisms of Feminist Standpoint Theory. Longino (1993b) argues that standpoint theory cannot provide a noncircular basis for deciding which standpoints have epistemic privilege. Stevens (2000) argues that in Marxist theory, the transhistorical necessity of relations of production, and the universalizability of these relations, grounds the epistemic privilege of workers as the future universal class. But gender relations cannot be universalized, and race relations also lack transhistorical necessity, so neither the standpoint of women nor of black women can claim epistemic privilege. Bar-On (1993)

argues against grounding women's epistemic privilege in their oppression, via feminine cognitive styles. If the feminine ethics of care provides the epistemically privileged perspective on morality, then our access to moral knowledge is predicated on the continuation of existing gender relations, which produce this ethic. Grounding epistemic privilege in feminine cognitive styles therefore forces a choice between having ethical knowledge and living in a nonsexist society. Bar-On also claims that the center-periphery model that underwrites the epistemic privilege of workers does not apply to women. Marx held that class conflict is the central phenomenon that drives all other forms of group conflict, including sexism, racism, imperialism, and national and religious conflict. So understanding class could yield an understanding of other dimensions of inequality. It is no longer plausible to hold that *any* group inequality is central to all the others; they intersect in complex ways (Crenshaw 1999). This entails that women cannot even have privileged access to understanding their own oppression, since this takes different forms for different women, depending on their race, sexual orientation, and so forth. This critique has been forcefully developed by feminist postmodernists, who question the very possibility of a unified standpoint of women, and see, behind the assertion of a universal woman's viewpoint, only the perspective of relatively privileged white women (Lugones and Spelman 1983).

Feminist Postmodernism

General Postmodernist Themes. Postmodernism as a North American intellectual movement draws inspiration from a variety of French poststructuralist and postmodernist theorists, including Foucault, Lacan, Derrida, Lyotard, and Irigaray. It embodies a skeptical sensibility that questions attempts to transcend our situatedness by appeal to such ideas as universality, necessity, objectivity, rationality, essence, unity, totality, foundations, and ultimate Truth and Reality. It stresses the locality, partiality, contingency, instability, uncertainty, ambiguity and essential contestability of any particular account of the world, the self, and the good. Politically, the postmodernist emphasis on revealing the situatedness and contestability of any particular claim or system of thought is supposed to serve both critical and liberatory functions. It delegitimizes ideas that dominate and exclude by undermining their claims to transcendent justification. And it opens up space for imagining alternative possibilities that were obscured by those claims.

Although postmodernist themes are often expressed in an obscure jargon, they can be cast in terms more familiar to analytic philosophers. Postmodernists begin with ideas about language and systems of thought. They claim that (what we think of as) reality is "discursively constructed." This is the linguistic version of the now inescapable (!) Kantian thought that our minds grasp things not as they are "in themselves" but only through concepts, signified by words. "The linguistic sign acts reflexively, not referentially" in a "discursive field." This is a version of radical meaning holism: signs get their meaning not from their reference to external things but from their relations to all of the other signs in a system of discourse. Meaning holism entails that the introduction of new signs (or elimination of old ones) will change the meanings of the signs that were already in use. Signs therefore do not have a fixed meaning over time. This is a Heraclitean version of historicism: we cannot step into the same stream of thought twice. Together, these ideas support the "rejection of totalizing metanarratives." There can be no complete, unified theory of the world that captures the whole truth about it. Any such theory will contain

a definite set of terms. This entails that it cannot express all conceptual possibilities. For a discourse that contained different terms would contain meanings not available in the discursive field of the theory that claims completeness. Thus, the selection of any particular theory or narrative is an exercise of "power" -- to exclude certain possibilities from thought and to authorize others.

Postmodernism extends these ideas about language to social practices more generally. The key idea underwriting this extension is that actions and practices are linguistic signs. Like words, they signify things beyond themselves by means of linguistic devices such as metaphor and metonymy. For example, the elevation of the judge's bench metaphorically signifies his superior authority over everyone else in the courtroom. This permits an analysis of social practices and behaviors as exhibiting the same structure and dynamics as language itself. Just as words get their meaning from their relations to other words rather than from their relation to some external reality, so do actions get their meaning from their relations to other actions, rather than from their relation to some pre-linguistic realm of human nature or natural law. Thus, the superior authority of the judge consists in the conventions of deference others manifest in their actions toward him. It is not underwritten by a supposed natural tendency of humans to obey authority, or by an underlying normatively objective authority. The latter thoughts express essentialist and objectivist power plays, attempts to foreclose contests over practices by fixing them in a supposedly extra-linguistic reality. Such attempts are not only objectionable but futile, because the meanings of actions are constantly being subverted by other actions that, in changing the context of the former actions, changes their meanings. This is why postmodernists celebrate ironic, parodic, and campy renditions of conventional behaviors as politically liberating (Butler 1993). If Marx lamented that history repeats itself twice -- first as tragedy, second as farce -- postmodernists revel in the same process.

Postmodernists view the self as likewise constituted by signs that have meaning only in relation to other signs. There is no unified self that underlies the play of a stream of signifiers. This is a linguistic version of Hume's fragmented stream-of-consciousness account of the self, but with a social twist. Signs, unlike Hume's simple ideas, form language, which is socially constructed. Thus, although subjectivity is constituted through the production of signs, the self is not free to make of these whatever it wants, but finds itself entangled in a web of meanings not of its own creation. Our identities are socially imposed, not autonomously created. However, this does not foreclose the possibility of agency, because we occupy multiple social identities (e.g., a woman might be a worker, a mother, lesbian, Mexican, and so forth). The tensions among these conflicting identities open up spaces for disrupting the discursive systems that construct us.

Because, in its philosophy of language, words refer to concepts rather than things in the world, postmodernism reproduces in linguistic terms some of the same epistemological conundrums posed in the history of modern philosophy by the veil of ideas. This generates a tendency toward idealism in both traditions. However, given the constant flux of meanings generated by holism, these tendencies cannot secure the certainty or stability that empiricists thought they could attain by resorting to idealism. The more careful practitioners of postmodernism resist wholesale idealism. Claims that bodies, matter, or the objects investigated by the natural sciences are "discursively constructed" or "socially constructed" do not assert that the external world would disappear if people stopped talking about it. Rather, they assert a kind of nominalism: that the world does not dictate the categories we use to describe it, that innumerable

incompatible ways of classifying the world are available to us, and therefore that the selection of any one theory is a choice that cannot be justified by appeal to "objective" truth or reality. Even the ways we draw our distinctions between mind and body, ideas and objects, discourse and reality, are contestable.

Feminist Postmodernism. Within feminism, postmodernist ideas have been deployed against theories that purport to justify sexist practices -- notably, ideologies that claim that observed differences between men and women are natural and necessary, or that women have an essence that explains and justifies their subordination. The oft-cited claim that gender is socially or discursively constructed -- that it is an effect of social practices and systems of meaning that can be disrupted -- finds one of its homes in postmodernism (Butler 1990). However, postmodernism has figured more prominantly in internal critiques of feminist theories. One of the most important trends in feminist thinking in the past twenty years has been exposing and responding to exclusionary tendencies within feminism itself. Women of color and lesbian women have argued that mainstream feminist theories have ignored their distinct problems and perspectives (Collins 1990; Hull, Scott and Smith, 1982; Lorde 1984). Feminist postmodernism represents both a vehicle for and response to these critiques. It underwrites a critique of the concept "woman" -- the central analytical category of feminist theory. And it proposes perspective-shifting as a strategy for negotiating the proliferation of theories produced by differently situated women.

The critique of the concept "woman." Feminist postmodernists have criticized many of the leading feminist theories of gender and patriarchy as essentialist (Butler 1990, Flax 1990, Spelman 1988). Essentialism here refers to any theory that claims to identify a universal, transhistorical, necessary cause or constitution of gender identity or patriarchy. The objection to essentialism is fundamentally political: in claiming that gender identity is one thing or has one cause, such theories convert discursively constructed facts into norms, difference into deviance. They either exclude women who don't conform to the theory from the class of true "women," or else represent them as inferior. The critiques of feminist theories by lesbian women and women of color have reinforced skepticism about the unity presumed in the category "woman" by highlighting the intersectionality of identities of gender, race, class, and sexual orientation. The chief faultlines for the fragmentation of the category "woman" have thus been the other identity formations along which social inequalities are constructed.

This critique of "woman" as a unified *object* of theorizing entails that "woman" also cannot constitute a unified *subject* of knowing (Lugones and Spelman 1983). The theories of universal gender identity under attack are ones in which the authors, all white middle class heterosexual women, could see themselves. Critics claim that the authors fail to acknowledge their own situatedness and hence the ways they are implicated in and reproduce power relations -- in this case, the presumptuous authority of white middle class heterosexual women to define "the standpoint of women" -- to speak for all other women and define who they are. Feminist standpoint theorists, who claim an epistemic privilege on behalf of their standpoint, are thereby unmasked as asserting a race and class privilege over other women.

Feminist postmodernists draw two lessons from this critique. First, universal claims about women, gender, and patriarchy should be avoided. Second, feminist standpoint theory's project of identifying a single epistemically privileged perspective is fundamentally flawed, an unjustified assertion of power in the name of an unattainable objectivity. This lesson applies to subaltern feminist standpoints as well. The

assertion of a black feminist standpoint, for example, objectionably essentializes black women. Once the postmodernist critique of essentialism is granted, there is no logical stopping point in the proliferation of perspectives.

Perspective shifting. Feminist postmodernism thus envisions our epistemic situation as characterized by a permanent plurality of perspectives, none of which can claim objectivity -- that is, transcendence of situatedness to a "view from nowhere." This position has sometimes been characterized as relativist. Haraway (1991) replies that it rejects both objectivism and relativism for the ways they let knowers escape responsibility for the representations they construct. To claim objectivity for a representation is to claim that "the world made me represent things this way." To claim relativism is to claim that "my identity (my situation) made me represent things this way (and my identity/situation is not inferior to yours)." Both positions disclaim the active participation of the knower in constructing her representations. Even a photograph, the paradigm of an "objective" representation, reflects the photographer's choice of film, lenses, frames, exposure, and so forth. But the resort to a relativism of identity is no better. In asserting the equality of all perspectives, it claims immunity from the critiques of differently positioned others, and complacency in one's own position. Although it acknowledges the dependence of a knower's representations on the particulars of her situation, it claims that she had no choice about that. Postmodernists, however, reject the fixity and unity of personal identity on which relativism rests. People are not epistemically trapped inside their cultures, their gender, their race, or any other identity. They can choose to think from other perspectives. Thus, although we will always have a plurality of perspectives, their constitution is constantly shifting rather than static, and there is no stable correspondence between individuals and perspectives.

Negotiating the bewildering array of situated knowledges therefore involves two types of epistemic practice. One is acceptance of responsibility, which involves acknowledging the choices of situation that entered into the construction of one's representations (Haraway 1991), and considering how one's situation affects the content of one's representations (Harding 1993). The second is "world traveling" (Lugones 1987) or "mobile positioning" -- trying to see things from many other perspectives. Mobile positioning can never be transparent or innocent. Imagining oneself in another's situation is full of risks. It requires sensitive engagement with and sympathy for the others who occupy those positions. Both transform situated knowing into a critical and responsible practice.

Criticisms of Feminist Postmodernism. Both key features of feminist postmodernism -- the rejection of "woman" as a category of analysis, and the infinite fragmentation of perspectives -- are controversial within feminist theory. A wholesale opposition to large-scale generalizations about women seems to arbitrarily preclude a critical analysis of large-scale social forces that critically affect women (Benhabib 1995). That women in different social positions may experience sexism differently does not entail that they have nothing in common -- they still suffer from sexism (MacKinnon 2000). Intersectionality, rather than being a basis for dissolving the category "woman," may be accommodated through a structural analysis of gender that allows for racialized and otherwise particularized modes of sexist oppression (Haslanger 2000). The postmodernist alternative of fragmentation and multiplicity threatens both the possibility of analytical focus (it is impossible to keep all axes of difference in play at once) and of politically effective coalition building among women with different identities. Carried to its logical

conclusion, feminist postmodernism dissolves all groups, thereby reproducing the individualism of the Enlightenment epistemology it claims to repudiate. And the idea of mobile positioning may simply reproduce the objectivism and ideas of autonomy that postmodernists claim to reject, only now in the guise of "the view from everywhere" rather than "the view from nowhere" (Bordo 1990). Critics argue that feminists would do better if they forthrightly appropriated ideals of human rights and autonomy, rather than embracing "the death of the subject" in the fragmentation of the self (Benhabib 1995). Despite these difficulties, postmodernism remains a powerful current in feminist epistemology, due to the acknowledgment by all feminists that a plurality of situated knowledges appears to be an inescapable consequence of social differentiation and embodiment.

Feminist Empiricism

Relations of Feminist Empiricism to Empiricism in general. Empiricism is the view that experience provides the sole, or at least the primary, justification for all knowledge. From the classical empiricists to some early twentieth-century theorists, empiricists held that the content of experience could be described in fixed, basic, theory-neutral terms -- for example, in terms of sense-data. Most also regarded philosophy as a discipline that could provide a transcendent or external justification for empirical or scientific methods. Quine revolutionized empiricism by rejecting both of these ideas. For Quine, observation is thoroughly theory-laden. It is cast in terms of complex concepts that cannot be immediately given in experience, all of which are potentially subject to revision in light of further experience (Quine 1963). And epistemology, far from providing an extrascientific vindication of natural science, is simply another project within science, in which we empirically investigate our own practices of inquiry (Quine 1969). In these two respects, feminist empiricists are the daughters of Quine. However, Quine accepted a sharp division between facts and values that feminist empiricists argue cannot be sustained within a thoroughly naturalized empiricism. Feminist empiricists are deeply engaged in considering how feminist values can legitimately inform empirical inquiry, and how scientific methods can be improved in light of feminist demonstrations of sex bias in currently accepted methods. Their version of naturalized epistemology therefore does not follow Quine in reducing epistemology to nonnormative psychological investigations, but rather upholds the roles of value judgments in rigorous empirical inquiry (Campbell 1998, Nelson 1990). Quine also presupposes an individualist account of inquiry; his preferred reduction basis for naturalized epistemology is behavioral and neuro- psychology. Feminist empiricists are concerned with the impact on inquiry of social practices relating to gender, race, class and other bases of inequality. They therefore take sociology, history, and science studies seriously. Most also advocate a socialized epistemology, in which inquiry is treated as a fundamentally social process and the basic subjects of knowledge may even be communities or networks of individuals.

The Paradoxes of Bias and Social Construction. The central problematics of feminist empiricism can be captured in two apparent paradoxes. First, much feminist science criticism consists in exposing the androcentric and sexist biases in scientific research, especially in theories about women, sexuality, and gender differences. The force of this criticism seems to rest on a prior empiricist commitment to the view that bias is epistemically bad -- that it leads to false theories. Yet, advocates of feminist science urge that feminist values inform scientific inquiry. This amounts to a recommendation that science incorporate

certain biases into its operations. Feminist empiricists need to reconcile these conflicting claims. This is known as the paradox of bias. Second, and relatedly, much feminist science criticism is devoted to exposing the influence of social and political factors on scientific inquiry. Scientists advocate androcentric and sexist theories because they are influenced by the sexist values of the wider society. This would seem to imply that, to eliminate these social biases, feminists adopt an individualist epistemology. Instead, feminist epistemologists stress the social construction of knowledge. They urge, not that inquirers insulate themselves from social influcences, but that they restructure scientific practices to be open to *different* social influences. This can be called the paradox of social construction.

Feminist empiricists argue that the key to dissolving both paradoxes is to undermine the assumptions that underlie them: that biases, political values, and social factors can influence inquiry only by *displacing* the influence of evidence, logic, and whatever other purely cognitive factors tend to lead to true theories. Not all bias is epistemically bad (Antony 1993). There are three general strategies for showing this, which may be called pragmatic, procedural, and moral realist. The pragmatic approach stresses the plurality of aims that inquiry serves. Inquiry seeks truths, or at least empirically adequate representations, but *which* truths any particular inquiry seeks depends on the uses to which those representations will be put, many of which are practical and derived from social interests. The paradoxes are dissolved by showing how responsible inquiry respects a division of labor between the functions of evidence and social values -- the evidence helping inquirers track the truth, the social values helping inquirers construct representations out of those truths that serve the pragmatic aims of inquiry (Anderson 1995b). This view may be joined with a view of nature as rich, complex, and messy. No single theory captures the whole structure of reality, since different ways of classifying phenomena will reveal different patterns useful to different practical interests (Longino 2001). The procedural approach argues that epistemically bad biases can be kept in check through an appropriate social organization of inquiry. A social organization that holds people with different biases accountable to one another will be able to weed out bad biases, even if no individual on her own can be free of bias (Longino 1990). This view may be joined with the idea that the subject of knowledge (Nelson 1993), epistemic rationality (Solomon 1994) or objectivity (Longino 1990, 2001) is the epistemic community, not the individual. The moral realist approach argues that moral, social and political value judgments have truth-values, and that feminist values are true. Inquiry informed by feminist values therefore does not displace attention to the evidence, because the evidence vindicates these values (Campbell 1998).

Feminist empiricists appeal to the pragmatist tradition to undermine the sharp dichotomy between fact and value (Antony 1993; Nelson 1993). They argue (compatibly with other pragmatists, such as Hilary Putnam), that Quine's arguments about the underdetermination of theory by evidence lead to a view of facts as partially constituted by values, and values by facts. In the absence of a sharp distinction between facts and values, it cannot be argued that inquiry explicitly motivated by feminist values is *in principle* opposed to the truth. Whether any particular feminist, or sexist, theory is true or false will depend on empirical investigation informed by epistemic norms -- norms which may themselves be reformed in light of the merits of the theories they generate. This is the project of naturalized epistemology, whereby the vindication of norms of inquiry is sought not outside, but within, ordinary empirical investigation. Feminist empiricist investigations of the interaction of facts and values are further discussed below. Feminist empiricist explorations of how norms of inquiry should be constituted to enhance objectivity are

also discussed below.

Criticisms of Feminist Empiricism. Within feminist theory, the intellectual traditions and training of standpoint and postmodernist epistemologists have not kept track of the radical changes in the empiricist tradition inspired by Quine and further developed by feminist empiricists. Consequently, some criticisms of what is called "feminist empiricism" by other feminist theorists do not fit what feminists who call themselves "feminist empiricists" believe. For example, feminist postmodernists criticize feminist empiricists for presuming the existence of an individual, transhistorical subject of knowledge outside of social determination (Harding 1990), even though the naturalized epistemology that feminist empiricists adopt has long since abandoned that conception of knowers in favor of viewing knowers as socially situated. Feminist empiricists are also criticized for accepting an uncritical concept of experience (Scott 1991), even though feminist empiricists accept the theory- and value-laden character of evidence and hence the critical revisability of descriptions of experience in light of new evidence, theoretical, and normative reflections. Feminist empiricists have also been criticized for naively holding that that science will correct the errors and biases in its theories about women and other subordinated groups all by itself, without the aid of feminist values or insights (Harding 1986, 1991). This contrasts with the actual position of those who call themselves feminist empiricists, who argue that science cannot claim to attain objective knowledge of gendered beings or our gendered social world without actively including feminist inquirers as equals in the collective project of inquiry (Longino 1993a, 1993b). More pointedly, the standpoint theorist Hundleby (1997) criticizes feminist empiricism for overlooking the vital role of feminist political *activity*, in particular, the development of oppositional consciousness, as a superior source of hypotheses and evidence for challenging sexist and androcentric theories.

Feminist Science Criticism and Feminist Science

The history of feminist interventions into most disciplines follows a common pattern. Feminist inquiry begins as a critique of accepted disciplinary methods, assumptions, and canons. As it matures, it develops constructive projects of its own. The history of feminism and science follows this pattern. In the empirical sciences, the pattern helps us see how feminist epistemology negotiates the tension between the two poles in the paradox of bias that lies at the core of the feminist empiricist project. Feminist science critics focus on identifying androcentric and sexist biases in the actual practice of science. This practice began by representing bias as a source of error. But as philosophers and historians of science joined the practice of feminist science criticism, they developed a more sophisticated way of understanding some biases as epistemic resources. Advocates of feminist science develop this theme in seeking to practice science in light of and in the service of feminist aims and values. They thereby represent feminist biases as epistemic resources.

Feminist Science Criticism: Bias as Error. Feminist science criticism originated in the critiques that working biologists, psychologists, and other scientists made of the androcentric and sexist biases and practices in their own disciplines -- especially of theories about women and gender differences that legitimate sexist practices. Exemplary works in this tradition include Bleier (1984), Fausto-Sterling (1985), Hrdy (1981), Leacock (1981), Sherif (1987), and Tavris (1992). The criticism takes many forms.

(1) Studies of how the exclusion or marginalization of women scientists impair scientific progress. For example, the failure to provide Barbara McClintock with professional standing, resources, and access to graduate students delayed incorporation of her pioneering discoveries of genetic transposition into mainstream biology (Keller 1983). (2) Studies of how the applications of science and technology disadvantage women and other vulnerable groups, treat their interests as less important, or express contempt for them. Examples include eugenics (Hubbard 1990), and economic development policies that reinforce gender hierarchy by offering training and resources to men, but not women, in developing countries (Waring 1990). Such practical ill-effects of science applications can be traced in part to epistemic defects in the underlying science -- to bogus concepts of race in the case of eugenics, and to failures to recognize women's work as contributing to the "economy" in the case of sexist development policies. (3) Studies of how science has ignored women and gender, and how turning attention to these issues may require revisions of accepted theories. Hays-Gilpin and Whitley (1998) document particularly dramatic examples of this in the field of archaeology. (4) Studies of how biases toward working with "masculine" cognitive styles -- for example, toward centralized, hierarchical control models of causation as opposed to "feminine" (contextual, interactive, diffused) models -- have impaired scientific understanding, for example, in studies of slime-mold (Keller 1985b) and molecular biology (Spanier 1995). (5) Studies of how research into sex differences and women's and men's "natures" that reinforces sex stereotypes and sexist practices fail to live up to standards of good science -- for example, in drawing inferences on the basis of miniscule sample sizes or correlations not tested against an appropriately designed control group, or in ignoring disconfirming data (Fausto-Sterling 1985, Tavris 1992). Gender bias may also be revealed in the conceptual framework of the theory in question -- for example, in representing subjective gender identification as a dichotomous variable, thereby eliminating other possibilities, such as androgyny, from consideration (Bem 1993).

In all of these cases, gender bias is represented as a cause of error, or at least delay in recognizing the truth. But, as philosophers and historians of science joined the practice of feminist science criticism, alternative models of gender bias were developed, sometimes in cooperation with working scientists. Exemplary works of feminist science criticism by philosophers and historians of science include Haraway (1989), Harding (1986, 1991, 1993, 1998), Lloyd (1993), Longino and Doell (1983), Schiebinger (1989), and Wylie (1996). Although some of this work is devoted to exposing errors caused by sexist and androcentric bias, some of it is devoted rather to showing how the interests in technological control that underlie the modern practice of science limit its scope and what it takes to be significant knowledge (Lacey 1999, Merchant 1980, Tiles 1987). Another core project of feminist science criticism is demonstrating that the evidence assembled on behalf of the theories under study does not compel assent to the theories. The theories go well beyond the data that support them, with the gap being filled by sexist and androcentric assumptions. Thus, Haraway (1989) uses the tools of literary theory to demonstrate how hypotheses in primatology and evolutionary theory depend on narrative conventions (for example, casting the transition from ape to hominid as a heroic drama) and tropes (for example, casting primates as mirrors of human nature). While these narrative conventions and tropes have considerable persuasive power, their appeal is rhetorical, and the evidence does not compel their selection. Beyond this negative critique, feminist science critics are interested in uncovering and defending the viability of alternative nonsexist and feminist theories of the phenomena in question. When they operate in this mode, the critics are not claiming that sexist and androcentric theories are false, but rather that they are not proven or

established, because at this stage in the development of the evidence, legitimate and at least equally viable rivals exist.

To sort out these different accounts of the cognitive role of gender bias, it is helpful to distinguish four dimensions in the evaluation of research programs: (1) conceptual criticism; (2) methodological criticism; (3) evaluating the relation of the available evidence to the program's hypotheses (does the evidence tend to confirm or disconfirm them?); (4) *comparing* the program's theory to rival theories in terms of their empirical adequacy and other epistemic values. Bias in a research program is revealed as *error* to the extent that it is shown to generate or rest on (1) confused or nonreferring concepts that purport to refer (for example, the concept of "race" as biological subspecies of human beings); (2) violation of valid methodological principles; (3) belief in a theory in the face of a lack of evidential support for it, or strong evidence against it; or (4) continued commitment to a theory with some evidential support, even when some rival theories dominate it with respect to *all* epistemic values, including empirical adequacy. Biases shown to generate error in this way should be stopped, through better training of scientists or the adoption and enforcement of methodological principles designed to check their influence. Feminist science criticism in the bias-as-error mode parallels the heuristics-and-biases tradition of psychology (Kahneman, Slovic and Tversky 1982), a tradition which has already been taken up in naturalized epistemology and philosophy of science (e.g., Solomon 1994). On a normative level, it generates methodological principles for engaging in nonsexist science. Exemplary normative (methodological) works generated by feminist science criticism include Altmann (1974) and Eichler (1988).

Bias in a research program is shown to be *limiting* or *partial*, but not necessarily erroneous, to the extent that avoids clear error and generates (1) a limited range of concepts and/or (2) uses a limited range of methods, (3) has some empirical successes, while (4) rival theories, depending on different concepts and/or methods, can also claim to avoid clear error and to possess some empirical successes or other epistemic virtues not possessed by the research program in question. Such biases are *legitimate*: it is rationally acceptable to conduct scientific inquiry under the influence of such biases. Indeed, empirical investigations into the workings of the human mind strongly suggest that we have no choice but to think in accordance with some biases (Chomsky has shown, for example, that we have innate ideas of deep grammatical structures). Moreover, the underdetermination of theory by data implies that without some biases, we would be unable to make sense of our world at all (Antony 1993). When biases are partial but not clearly erroneous, they serve a positive *generative* function: they produce new concepts, methods, and hypotheses that open up new aspects of the world for understanding. They are *resources* for enhancing our grasp of the world. From a normative point of view, feminist philosophers of science argue that we have an epistemic interest in ensuring that certain limiting biases do not dominate research *to the exclusion of other generative biases that would generate rival theories possessing a different range of important empirical successes.* The point in exposing the androcentric and sexist biases lying behind certain research theories is not to show that they are false (they might in the end be empirically vindicated), but to make salient the room for alternative programs not based on such biases.

Feminist Science: Bias as Resource. Most advocates of *feminist science* argue, in this vein, that scientific inquiries informed by feminist values are based on legitimate, generative limiting biases. They argue not that feminist sciences should exclude other ways of doing science, but that feminist sciences

should be included as among the legitimate choices available to investigators. This picture of science is pluralistic, compatible with the postmodern rejection of "totalizing narratives," but more inclined than postmodernists to explain the persistence of pluralism in the social and applied sciences in scientific realist terms: science is disunified because the world is rich with a multitude of cross-cutting structures, which no single theoretical vocabulary can capture. Different communities have interests in different aspects of reality, so leaving them free to follow their interests will reveal different patterns and structures in the world (Harding 1998; Longino 2001).

Against this pluralistic view, some advocates of feminist science define it in terms of adherence to specific ontologies and methodologies expressing a "feminine" cognitive style (Duran 1991, Keller 1983, 1985a). On this conception, for example, the content of any feminist theory should have a relational rather than an atomistic ontology, favor the concrete over the abstract, avoid generalizations about women in favor of exposing the richness and particularity of different women's lives and perspectives, and so forth. Its methods should encompass intuition, emotional engagment, and other cognitive styles associated with a feminine sensibility. This view has had perhaps its greatest impact in feminist works attacking quantitative methods in the social sciences. For example, Stanley and Wise (1983) argue that only qualitative methods that accept women's reports of their experiences in their own terms, refusing to generalize, can uphold feminist values of respecting differences among women and avoiding the replication of power differences between researchers and research subjects.

Pluralist feminist scientists and philosophers of science have vigorously contested these attempts to define feminist science in terms preferred content and "feminine" method. They argue that many questions of interest to feminists are best answered with quantiative methods (Jayaratne and Stewart, 1991), and indeed that feminists may properly make use of a wide range of methods (Harding 1987, Nielsen 1990, Reinharz 1992). Feminist science is not defined by its content, but rather by the pragmatic interests that generate the questions it asks. (Sometimes this distinction is cast as one between "feminist science" and "doing science as a feminist.") Feminists are interested in uncovering the causes of women's oppression, revealing the dynamics of gender in society, and producing knowledge that women can use to overcome the disadvantages to which they are subject. Forms of knowledge that simply valorize the "feminine" may not be helpful to women who would be better off not having norms of femininity imposed on them. In any event, feminist pluralists argue that advocates of "feminine" science have not shown that feminine cognitive styles and ontologies are, as a general matter, better able to track the truth (Longino 1989).

If feminist science amounts to "doing science as a feminist" -- that is, using science to answer questions generated by feminist interests -- one may ask whether it differs in any substantive respect from the science that is already practiced by nonfeminists. Feminist pluralists reply that scientific practice is already highly disunified; philosophies of the special sciences reveal great variations in methods, background assumptions, sources of evidence, cognitive values, and interpretive strategies (Longino 2001). So the dichotomy between feminist and mainstream science presupposed by the question is false. Doing biology, primatology, anthropology, archaeology, psychology, economics, history or any other special science as a feminist -- that is, with the aim of answering feminist questions -- has resulted in many and various *local* methodological innovations, discoveries of new sources of evidence, and

developments of alternative theories (see, for example, Bell, Caplan and Karim 1993; Haraway 1989; Hays-Gilpin and Whitley 1998; Nielsen 1990). These are then made available to inquirers asking other, nonfeminist questions. Thus, there is no presumption that certain methods, evidence, etc. are uniquely available to serve feminist cognitive interests.

Nevertheless, there are some common threads in "doing science as a feminist" that *tend* to favor certain types of representation over others (Longino 1994). Feminists are interested in epistemic practices that reveal the operations of gender in the world, and opportunities for women to resist and transform these operations. One way gender bias operates to reinforce sexism is through the perpetuation of categorical, dichotomous thinking which represents masculinity and femininity as "opposites," femininity as inferiority, and nonconformity to gender norms as deviant. This gives feminists an interest in the value of "ontological heterogeneity" -- using categories that permit the observation of within-group variation and that resist the representation of difference from the group mean as a form of deviance. Gender bias also reinforces sexism through single-factor causal models that attribute seemingly intrinsic powers to men by neglecting their wider context. The value of "complexity of relationship" favors the development of causal models that facilitate the representation of features of the social context that support male power, including female participation and complicity. Other feminist cognitive values involve the *accessibility* of knowledge: feminist favor knowledge that "diffuses power" in being cast in a form usable to people in subordinate positions, who usally lack technical expertise and access to expensive equipment. This interest underlies the appropriate technology movement in developing countries. For similar reasons, feminists are more interested in knowledge applicable to meeting human needs than in research programs with little prospect of advancing these interests. These values are feminist in the sense of advancing feminist interests, but their usefulness is not confined to feminism. None of these feminist cognitive values displace or compete with the search for truth, because doing science as a feminist, like doing science with any other interest in mind (for example, medical or military interests) involves commitment to the cognitive value of producing empirically adequate theories.

Feminist Defenses of Value-Laden Inquiry

The Challenge of Value-Neutrality. The theory and practice of feminist science raises the question of how any inquiry shaped by moral, social, and political interests can simultaneously be faithful to the fundamental epistemic interest in truth. Against the project of feminist science, many philosophers hold that true science is neutral among social, moral, and political values. Lacey (1999) usefully distinguishes the following claims of value-neutrality: (1) *Autonomy*: science progresses best when uninfluenced by social/political movements and values. (2) *Neutrality*: scientific theories do not imply or presuppose any judgments about noncognitive values, nor do scientific theories serve any particular noncognitive values more fully than others. (3) *Impartiality*: The only grounds for accepting a theory are its relations to the evidence. These grounds are impartial among rival noncognitive values.

Of these claims, neutrality is the most dubious, because it depicts the grounds for accepting social, political and moral values as utterly detached from evidence about human potentialities and about what happens when people try to realize these values in practice. If this were true, then the defenders of

keeping mathematics a male preserve would not have bothered arguing that women were not intellectually capable of doing mathematics and that their uteri would wander if they tried to do it -- and feminists would not have bothered disputing those claims. Neutrality is less a claim about the character of science than about the justification of social and political values. As a categorical claim about the latter, it is false. Taylor (1985) and Tiles and Oberdiek (1995) show, in detailed case studies, how scientific theories do serve some social and political values more than others.

The core claim of value-neutrality, however, is impartiality. The thought that underwrites impartiality is that scientific theories aim at the truth, at what *is* the case, whereas value judgments deal with what *ought* to be the case. Even if neutrality is false, because facts constitute part of the warrant for value judgments, the converse is not true. Only facts can supply the warrant for other facts. Autonomy, in turn, is defended as a means to ensure that science satisfies the demands of impartiality. Social and political movements are thought to threaten autonomy because their primary influence on science is thought to consist in pressuring scientists to ignore the facts and validate their worldviews. Defenders of impartiality object to the very idea of feminist science because they view it as threatening impartiality.

The Basic Underdetermination Argument. Feminist empiricists reply to the challenge of value-neutrality by extending Quine's argument that theory is underdetermined by evidence (Longino 1990, Nelson 1993). Any body of observations counts as evidence for particular hypotheses only in conjunction with certain background assumptions. Vary the background assumptions, and the same observations will support quite different hypotheses. For example, the failure to observe stellar parallax in the 17th century was taken as evidence that the Earth stands still by geocentrists, and as evidence that the stars are very far away by heliocentrists. No logical principle stops scientists from choosing different background assumptions against which to interpret their observations. In practice, scientists face some constraints in the selection of background assumptions, based on cognitive values such as simplicity and conservatism (resistance to revising deeply entrenched assumptions on which many other beliefs depend). But these cognitive values rarely reduce the scope for choice down to one option, and their interpretation and weights are contestable in any event (geocentrism was overturned only by overriding conservatism). Feminist empiricists conclude that, given the scope for choice in background assumptions, nothing stops scientists from selecting their background assumptions on account of their fit with social and political values, or indeed any other preference or interest. It follows that feminist scientists may select their background assumptions on account of their fit with feminist values.

Putnam (1981) has advanced a similar argument, carried to feminist conclusions by Nelson (1993). Value judgments operate like factual judgments in the web of belief, such that values judgments figure in the background assumptions that support factual judgments, and vice-versa. If the web of belief integrates judgments of fact and of value, then there is no clear distinction between these two judgment types. So there is no good argument against permitting feminist values to shape scientific judgments.

The underdetermination argument pries open a *potential* space for social values in science. But it is not sufficient to demonstrate the legitimacy of any *particular* ways of introducing feminist values into science. Feminist science critics and feminist scientists agree that there are cognitively illegitimate as well as cognitively legitimate ways for social values to influence science. That is the basis for

distinguishing error-generating biases from biases that serve as cognitive resources, a distinction required to dissolve the paradox of bias. Standing alone, the underdetermination argument does not help us discriminate one from the other. Additional criteria are needed.

One lesson about what to look for can be drawn from earlier debates over the theory-ladenness of observation. It is now generally agreed that the theory-laden character of observations does not threaten their status as evidence for a theory, provided that the theories presupposed in those observations do not immediately include the very theory being tested by those observations. Circularity, at least of a narrow sort, should be avoided. Similarly, the chief danger of value-laden inquiry is a kind of circularity of wishful thinking. The value-laden character of the background assumptions linking evidence to theories should not foreclose the possibility of discovering that one's values are mistaken, because based on erroneous beliefs about human potentialities and the consequences of putting certain values into practice. (Notice that it makes sense to worry about the danger of wishful thinking only if the neutrality thesis is false.) If women really can't do math, or their uteri really do migrate when they try (causing hysteria, as the sexist theory held), the values incorporated into feminist science should not close off this possibility in advance. Although, in setting out to test these sexist hypotheses, women scientists presuppose their own mathematical competence, this does not preclude their discovering otherwise. They need only open their calculations to public criticism to keep this possibility alive. If their evidence disconfirms the sexist hypotheses, and their calculations survive public scrutiny, then they have not run a vicious circle.

The Basic Pragmatic Strategy. The above reflections provide a standard for determining when socially value-laden inquiry has gone wrong. But they do not explain what positive epistemic influence they could have. How could they function as an epistemic *resource?* Feminist epistemologists at this point stress the pragmatic functions of inquiry (Anderson 1995b). All inquiry begins with a question. Questions may be motivated not only by the purely cognitive interest of curiosity, but by various practical interests in understanding the nature and causes of situations one judges to be problematic, and in finding out how to improve those situations. The resulting product of inquiry -- a theory or set of systematically connected beliefs -- should therefore be shaped to these practical-cum-cognitive interests. The pragmatic aspects of inquiry introduce new dimensions of evaluation to theories. We can ask not only whether the theories are backed by sufficient evidence to warrant their acceptance, but whether they are cast in forms that are cognitively accessible to the situated knowers who want to use these theories, whether they are useful to these knowers (help them solve their problems), and whether they answer the questions they were designed to answer. A set of statements can be true, yet fail these pragmatic tests.

Even the staunchest defenders of the value-neutrality of science acknowledge that pragmatic factors legitimately influence the choice of objects of study. In this function, then, pragmatic interests, including social and political values, are epistemic resources: inquirers with different interests will study and make discoveries about different aspects of the world. But the defenders of value-neutral science contend that once inquirers decide where to cast their flashlight, what gets lit up is determined entirely by the nature of the world. Feminist epistemologists argue that the light of practical interests penetrates more deeply into what is discovered than this. Knowers (subjects) play a more active role in constituting the object of knowledge than the flashlight metaphor suggests. (This is one thing feminist epistemologists mean when they say they reject "the subject-object dichotomy".) "Constitution" has two senses, representational and

causal. In the representational sense, knowers constitute the object of knowledge in choosing the terms in which they represent it, and in defining the context in which it is represented as operating. If knowing is like seeing, all seeing is a form of "seeing as" -- and different interests will make us see the "same" things differently (Longino 1990). This is a straightforward implication of the fact of situated knowing. In the causal sense, some representations have a causal impact on what is represented. When what we are representing is *ourselves*, uptake of our self-representations will change who we are and what we do. This follows from our agency, which is the determination to govern ourselves by our self-understandings. This is sometimes what is meant by the claim that subjects, or their identities, are "socially constructed."

The basic pragmatic strategy for defending feminist science, or any inquiry shaped by social and political values, is to show how the pragmatic interests of that inquiry license or require a particular mode of influence of values on the process, product, and uptake of the product of inquiry, while at the same time leaving appropriate room for evidence to play its warranting role. Values and evidence play different, cooperative roles in properly conducted inquiry; values do not *compete* with evidence for the determination of belief (Anderson 1995b).

A Catalogue of Types of Legitimate Influence of Social Values in Science. One can examine the actual operation of particular values in particular scientific investigations and judge, on a case by case basis, whether the values are closing off the possibility of discovering unwelcome facts, leading scientists to reason in a vicious circle, or insulating their findings from critical scrutiny, or whether the values are enabling the discovery of new facts -- whether they are, in short, obstructing or facilitating the search for knowledge. Such judgments are contextual and subject to revision in light of new evidence. What follows is a catalogue of *types* of influence of social values that feminist epistemologists and philosophers of science have argued may *in principle* legitimately influence theory choice (although whether their influence is epistemically good or bad in a particular case requires further investigation).

Selection and weighting of cognitive values. Kuhn (1977) argued that scientists need to appeal to cognitive values to take up the slack between theory and evidence. His list of cognitive values included accuracy (empirical adequacy or truth), scope, simplicity, fruitfulness, internal consistency and consistency with other beliefs (conservatism). As we have seen above, Longino (1994) argues that feminists have reason to prefer theories that manifest other cognitive values, such as diffusion of power. Diffusion of power, like simplicity, is not a truth-oriented cognitive value. Both count as cognitive values because they make theories cognitively accessible, comprehensible to our finite minds. Diffusion of power recognizes that cognitive accessibility is relative to the situation of the knower. (Longino's characterization of other values of feminist science, such as ontological heterogeneity and complexity of relationship, as "cognitive" values is something of a misnomer -- these fit better under the rubrics of classification and models, below.) Both simplification and diffusion of power stand in tension with truth, in that theories that embody them not only ignore many complex, messy truths, but may even make false claims. Whether this is bad depends on whether the truths ignored or the inaccuracies embraced are *important*, and this can be judged only in relation to the interests of the investigator. All legitimate research programs must seek to incorporate the value of empirical adequacy, which requires at least that theories try to *approximate* the truth. But how much accuracy this requires depends on how much the expected usefulness of the knowledge will be compromised by larger margins of error. The situation and

pragmatic interests of the inquirer or of the potential users of a theory may therefore legitimately affect the selection and weighting of cognitive values in theory choice.

Standards of Proof. By convention, social scientists reject the null hypothesis (that observed results in a statistical study reflect mere chance variation in the sample) only for P-values < 5%, an arbitrary level of statistical significance. Bayesians and others argue that the level of statistical significance should vary, depending on the relative costs of type I error (believing something false) and type II error (failing to believe something true). In medicine, clinical trials are routinely stopped and results accepted as genuine notwithstanding much higher P-values, if the results are dramatic enough and the estimated costs to patients of not acting on them are considered high enough. (The cost of not providing a potentially effective treatment may be death, while the cost of providing a useless treatment may be small.) This practice explicitly incorporates social value judgments in the standard of proof required before results are accepted. Hare-Mustin and Maracek (1994) argue, by parallel reasoning, that whether studies that find gender differences, or that fail to find them, should be accepted depends on the relative costs of Alpha Bias (exaggerating differences) and Beta Bias (neglecting differences) in the context at hand.

Classification. The ways observed phenomena are classified may legitimately depend on the values of the researcher. In medicine, the distinction between health and disease reflects moral judgments about human welfare and appropriate ways of dealing with problems, as well as judgments about causation. A condition regarded as bad for human beings is not classified as a disease unless some kind of medical therapy is considered both an appropriate and a potentially effective way to deal with it. Feminist inquiries, too, raise questions about the causes of women's oppression that require classifying phenomena as instances of rape, sexual objectification, sex discrimination, and so forth -- classifications all tied to their meeting both empirical and evaluative criteria (Anderson 1995a, 1995b).

Methods. The methods selected for investigating phenomena depend on the questions one asks and the kinds of knowledge one seeks, both of which may reflect the social interests of the investigator. Experimental methods in social science may be good for discovering factors that can be used to control people's behavior in similar settings. But to grasp their behavior as *action* -- that is, as attempts by agents to govern their behavior through their self-understandings -- requires different empirical methods, including qualitative interviews (which allow subjects to delineate their own systems of meaning) and participant observation. Standpoint theories, as critical theories, aim as well at empowering the subjects of study by helping them forge liberatory self-understandings, and these, too, may require different methods of inquiry -- for example, consciousness-raising (MacKinnon 1999).

Causal Explanations; Explanations of Meaning; Narratives. For most phenomena, the number of factors that have a causal impact on their occurrence is vast -- too large to comprehend or test in a single model. Investigators must therefore select a subset of causal factors to include in the models they test. This selection may be based on considerations of cost or availability -- some types of data are hard or expensive to get; cheap and accessible methods may be better suited to testing the causal influence of some variables than others. The selection of causal variables may also be based on fit with the social or personal interests of the investigator (Longino 1990, 2001). These interests often reflect background social and moral judgments of blame, responsibility, and acceptability of change. To take an innocuous

case, in most contexts, what is singled out as a cause of dangerous fires is a spark, flame, or flammable material, not the presence of oxygen. The items judged possible to change, or worth changing, are the focus of causal explanation. To take a more controversial case, conservatives are more likely to study divorce and out-of-wedlock birth as causes of women's poverty, whereas feminists are more likely to focus on other causes -- for example, the exclusion of women from better-paid jobs, the weak bargaining power of women in marriage, and norms of masculinity that induce fathers to avoid significant participation in child-rearing, thereby forcing women to forego earnings in taking up the slack. Notice that these causal explanations are not incompatible. All the causal factors cited may contribute to the feminization of poverty.

Often what inquirers seek is not merely a set of facts, but what the facts mean. Meaning holism implies that the meaning or signficance of facts depends on their relations to other facts. Even if two inquirers agree on the causal facts, they may still disagree about their meaning because they relate the facts in different ways, reflecting their background values. Feminists may agree with conservatives that divorce is a cause of the feminization of poverty, but deny that this means that women are better off married. They argue that marriage itself, with its gendered division of domestic and market labor, constitutes one of the major structural disadvantages women face, setting them up for worse outcomes in the event of divorce (Okin 1989). Conservatives, viewing marriage as an indispensible condition of the good life, are no more willing to view marriage in this light than most people would be willing to blame oxygen for the occurrence of house fires. It might be thought that scientists should stick to the facts and avoid judgments of meaning. But most of the questions we ask demand answers that fit facts into larger, meaningful patterns. Scientists therefore cannot help but tell stories, which require the selection of narrative frameworks that necessarily go beyond the facts (Haraway 1989). This selection may depend both on their fit with the facts and on their fit with the background values of the storyteller.

Framework Assumptions. As we ascend to higher levels of abstraction, very general framework assumptions come into play in constituting the object of study. Some of these are disciplinary. Economics studies humans as self-interested, instrumentally rational choosers. Social psychology studies humans as responding to socially meaningful situations. Behaviorism studies humans as controlled by objectively defined environmental variables. Behavioral genetics studies humans as controlled by their genes. These are all forms of "seeing as." Longino (1990) and Tiles (1987) argue that the selection of framework assumptions may depend on their fit with the interests of the inquirer. Feminists are interested in promoting women's agency, so they tend to prefer frameworks that permit the representation of women as agents. This selection does not guarantee that they will confirm the background assumption that women are agents. Causal models that include only agentic variables may not explain much of the variation in women's behavior; models that include both agentic and nonagentic variables may find that the latter explain all of the variation. The value-laden selection of framework assumptions need not lead to a vicious circle of reasoning, because it is still left up to the evidence to determine how successful the assumptions are in explaining the phenomena of interest.

Pluralism as the upshot of value-laden inquiry. Because the interests and values of inquirers vary, and inquirers select background assumptions in part for their fit with their interests and values, their background assumptions will also vary. Rather than lamenting this fact, feminist epistemologists urge us

to embrace it (Haraway 1991, Harding 1998, Longino 2001). A pluralism of theories and research programs should be accepted as a normal feature of science -- as it is, certainly, in the human sciences. As long as the different research programs are producing empirical successes not produced by the others, and avoiding clear error and viciously circular reasoning, there is good reason to treat the value-biases animating them as epistemic resources, helping us discover and understand new aspects of the world and see them in new perspectives, rather than as obstacles to the search for truth. Feminist science takes its place as one set of legitimate research programs among others, rather than as something that replaces the others. The price to be paid for this is the disunity of science. This does not imply relativism. Value-laden research programs are still open to internal and external critique. A naturalized epistemology that rejects neutrality allows that observations may undermine any background assumptions, including value judgments.

Trends in Feminist Epistemology

When Harding (1986) proposed her classification of feminist epistemologies into empiricism, standpoint theory, and postmodernism, she cast them as offering three fundamentally contrasting frameworks. Empiricism was thought to presuppose an unsituated, politically neutral subject of knowledge, whereas standpoint theory and postmodernism offered different approaches to the problem of situated knowledge -- the first upholding an epistemic privilege of one situation over others, the other embracing a relativism of standpoints. Trends in feminist epistemology in the last ten years have blurred the distinctions among feminist empiricism, standpoint theory, and feminist postmodernism -- trends Harding herself both predicted and advanced (1990, 1991, 1998). Most importantly, all three approaches to feminist epistemology embrace pluralism and reject totalizing theories. All three approaches also reject the traditional epistemological project of validating epistemic norms from a transcendent viewpoint, because they deny that there is any such viewpoint to be had.

Feminist standpoint theory. The postmodernist critique of standpoint theory, in conjunction with the proliferation of subaltern women's standpoints (black, Latina, lesbian, postcolonial, etc.) has led most standpoint theorists to abandon the search for a *single* feminist standpoint that can claim overarching epistemic superiority. Feminist standpoint theory has therefore moved in a pluralistic direction, acknowledging a multiplicity of epistemically informative situated standpoints (Harding 1991, 1998; Collins 1990). They claim that there are important things to learn from taking seriously the perspectives of all marginalized groups -- not just of various groups of women, but men and women in postcolonial societies, men and women of color, gay men, and so forth. A system of knowledge that draws on their insights and starts from their prediaments will be richer than one that draws only on the insights and starts from the predicaments of privileged groups alone (Harding 1993, 1998). This shifts the privilege claimed on behalf of subaltern standpoints from the context of justification to the context of discovery: thinking from subaltern standpoints is more *fruitful* than confining one's thinking to dominant perspectives. And the fruitfulness in question is judged more often on pragmatic grounds -- thinking from these standpoints enables us to envision and realize more just social relations (Hartsock 1996). At the same time, many standpoint theorists have focused more sharply on the epistemic value of the *experiences* of subordinated people (as opposed to making categorical claims about group differences in cognitive style). The shift to

pluralism represents a convergence with feminist postmodernism; the shift to pragmatism and experience, a convergence with feminist empiricism.

Feminist postmodernism. Wariness of the fractionating and centrifugal forces in postmodernism has led some feminists sympathetic to postmodernism to seek middle, more stable grounds that feminist empiricists, standpoint theorists, and postmodernists can share. Haraway (1989) stands out among feminist postmodernists for the tributes she pays to the achievements of feminist scientists working within empiricist standards of evaluation. She also seeks to reconstruct ideas of objectivity and epistemic responsibility consistent with situated knowledge (1991). Fraser (1995) and Fraser and Nicholson (1990) also urge a reformulation of the lessons of postmodernism, toward pragmatism, fallibilism, and contextualization of knowledge claims -- all features fully compatible with naturalized feminist empiricism -- as against categorical rejections of large-scale social theory, history, normative philosophy, and even humanist values. While it remains to be seen whether feminist postmodernists will actually take up these calls, they signal directions in which postmodernism could be taken.

Feminist empiricism. While early, nonphilosophical feminist science criticism by working scientists may have presupposed a naive version of empiricism, attempts by feminist epistemologists to make sense of feminist science criticism have, following Quine, incorporated explicitly pragmatist and naturalizing themes into feminist empiricism. Thus, feminist empiricists today stress the centrality of situated knowledge, the interplay of facts and values, the absence of transcendental standpoints, and the plurality of theories. These themes converge with those of postmodernism.

Remaining differences. The differences that remain among feminist postmodernists, empiricists, and standpoint theorists partially reflect different choices of tools. Feminist postmodernists use the tools of poststructuralism and literary theory. Feminist empiricists prefer the tools of analytic philosophy of science. Some versions of standpoint theory, such as Collins' (1990), rest on an identity politics alien to both postmodernists and empiricists. (To the extent that standpoint theory remains tied to a materialist epistemology, as in Hartsock (1996) and MacKinnon (1999), it is fully compatible with feminist empiricist naturalized epistemology.)

Other differences reflect different attitudes toward and conceptions of objectivity. Although feminist postmodernism has relativist tendencies, its skepticism and stress on instability undermines both the purportedly all-encompassing stance of objectivity and the self-contained, complacent parochiality of relativism. What's missing is not the thought that critique is possible, but any form of critique that enables one to build and synthesize rather than tear down and deconstruct claims to know. Although Haraway reconceives objectivity in terms of epistemic responsibility, it is hard to hold knowers accountable for their claims if they never stick to any claims for very long (Bordo 1990). Harding (1993, 1998) continues standpoint theory's project of trying to identify an epistemically superior approach that can claim "strong objectivity." Feminist empiricism offers an alternative procedural account of objectivity (Longino 2001). Both envision critical theory as a constructive, not just a deconstructive project. But standpoint theory remains residually attached to claims of epistemic superiority for feminist science, whereas feminist empiricism is concerned rather simply to make room at the pluralist table for feminist approaches to science, without asserting epistemic superiority on their behalf.

Charles Sanders Peirce

Charles Sanders Peirce (1839-1914) was the founder of American pragmatism (later called by Peirce "pragmaticism"), an extender of the Scotistic theory of signs (called by Peirce "semeiotic"), an extraordinarily prolific logician and mathematician, and a developer of an evolutionary, psycho-physically monistic metaphysical system. A practicing chemist and geodesist by profession, he nevertheless considered scientific philosophy, and especially logic, to be his vocation. In the course of his polymathic researches, he wrote on a wide range of topics, ranging from mathematical logic to psychology.

Brief Biography

Charles Sanders Peirce was born on September 10, 1839 in Cambridge, Massachusetts, and died on April 19, 1914 in Milford, Pennsylvania. His writings extend from about 1857 until near his death, a period of approximately 57 years. His published works run to about 12,000 printed pages and his known unpublished manuscripts run to about 80,000 handwritten pages. The topics on which he wrote have an immense range, from mathematics and the hard sciences at one extreme, to economics, psychology, anthroplogy, history of science, and the theory of signs, at the other extreme.

Peirce's father Benjamin was Professor of Mathematics at Harvard University and was one of the founders of the U. S. Coast and Geodetic Survey as well as one of the founders of the Smithsonian Institution. The department of mathematics at Harvard was essentially built by Benjamin. From Bejamin Peirce Charles Sanders Peirce received most of the substance of his early education as well as a good deal of intellectual encouragement and stimulation. Benjamin's didactic technique mostly took the form of setting interesting problems and checking Charles's solutions of them, and in this instructional atmosphere Charles learned his lifelong habit of thinking through problems entirely on his own. To this habit, perhaps, is to be attributed Charles Peirce's originality.

Peirce graduated from Harvard in 1859 and received the bachelor of science degree in chemistry in 1863. From 1859 until late 1891 he was employed by the U. S. Coast and Geodetic Survey, mainly doing geodetic investigations. From 1879 until 1884, Peirce maintained a second job teaching logic in the Department of Mathematics at Johns Hopkins University. At the time the Department of Mathematics was headed by the famous mathematician J. J. Sylvester. This job suddenly evaporated for reasons apparently connected with the fact that Peirce's second wife was a gypsy, and a gypsy moreover with whom he had apparently cohabited before marriage. This was Peirce's only academic employment, and after losing it Peirce worked thereafter only for the U. S. Coast and Geodetic Survey. This employment was lost in late 1891 because of funding worries generated in Congress. Thereafter, Peirce eked out a living doing odd-jobs and consulting work (mainly in chemical engineering and analysis). For the remainder of his life Peirce was often in dire financial straits, and sometimes he managed to survive only because of the charity of friends, for example William James.

At age 12 Charles read a standard textbook on logic by Bishop Richard Whately, and he began reading Immanuel Kant's *Critique of Pure Reason* at age 13. After three years of careful study of Kant, Peirce concluded that Kant's system was vitiated by what he called its "puerile logic," and about the age of 16 he formed the fixed intention of devoting his life to the study of and research in logic. Although it was impossible to earn a living as a research logician, his adoption of the profession of chemistry and his practice of the profession of geodesy allowed Charles to continue for many years to engage in researches on logic. One of his logical systems was the basis for Ernst Schroeder's three-volume treatise on logic, the *Vorlesungen ueber die Algebra der Logik*, and Peirce became widely regarded as the greatest logician of his day. By all who are familiar with his work he is considered one of the greatest logicians who ever lived.

Despite Peirce's early disagreements with Kant's position, Peirce continued to respect and read the first *Critique* throughout his life, and his ultimate philosophical position has much in common with the transcendental idealism of Kant, as well as with the objective idealism of Hegel. Like Kant, Peirce even

developed a set of ultimate categories (more on which later).

Difficulty of Access to Peirce's Writings

Peirce's extensive publications are scattered among various publication media, and have been difficult to collect. Shortly after his death in 1914, his widow Juliette sold his unpublished manuscripts to the Department of Philosophy at Harvard University. Initially they were under the care of Josiah Royce, but after Royce's death in 1916, and especially after the end of the First World War, the papers were poorly cared for. Many of them were misplaced, lost, given away, scrambled, and the like. Carolyn Eisele, one of several heroes in a great effort to locate and assemble Peirce's writings, reports having found a lost trunk of Peirce's papers only in the mid-1950's; it had, apparently for decades, been secreted in an unlit, obscure part of the basement in Harvard's Widener Library.

In the 1930's volumes of *The Collected Papers of Charles Sanders Peirce* began to appear, and for almost three decades these volumes, and collections of entries culled from them were the only generally available source for Peirce's thoughts. Unfortunately, many of the entries in the *Collected Papers* are not integral pieces of Peirce's own design, but rather pieces that were cobbled together by the editors from different Peircean sources. Often a single entry will consist of stretches of writing from very different periods of Peirce's intellectual life, and the stretches may be in tension or outright contradition with each other. Such entries not only make very difficult reading if one tries to regard them as consistent sustained passages of argument, but also tend to give a false picture of Peirce as unsystematic, desultory, and much more obscure than he really is.

The only intelligent way to publish the works Peirce is chronologically and with extremely careful editing. In such a fashion, entire Peircean works can be presented, and presented in their natural temporal setting. At last, but not until the 1980's, there began to appear such a chronological edition of carefully selected works of Peirce: the *Writings of Charles S. Peirce: a Chronological Edition*. Though currently somewhat slowed by lack of proper funding, the *Chronological Edition* has succeeded in covering quite well in five volumes the major writings from 1857 to 1886. This achievement is finally making it posssible to assess the real Peirce, and in particular the development of his thinking from its earliest to its later stages. Questions long vexed in Peirce scholarship are finally beginning to be debated usefully by Peirce scholars: whether there is genuine systematic unity in Peirce's thought, whether his ideas changed or developed over time and in what particulars his thought did change, when certain notions were developed by Peirce, whether there were definite "periods" in Peirce's intellectual development, what exactly Peirce meant by some of his more obscure notions such as his universal categories (on which see below).

Deduction, Induction, and Abduction

Prior to about 1865, thinkers on logic commonly had divided arguments into two subclasses: the class of deductive arguments (a.k.a. necessary inferences) and the class of inductive arguments (a.k.a. probable

inferences). About this time, Peirce began to hold that there were two utterly distinct classes of probable inferences, which he referred to as inductive inferences and abductive inferences (which he also called hypotheses and retroductive inferences). Peirce reached this conclusion by entertaining what would happen if one were to interchange propositions in the syllogism AAA-1 (Barbara): All M's are P's; All S's are M's; therefore, All S's are P's. This valid syllogism Peirce accepted as representative of deduction. But also seemed typically to regard it in connection with a problem of sampling theory. Let us regard being an M as being a member of a population of some sort, say being a ball of the population of balls in some urn. Let us regard P as being some property a member of this population can have, say being red. And, finally, let us regard being an S as being a member of a random sample taken from the population. Then our syllogism in Barbara becomes: All balls in this urn are red; All balls in this particular random sample are taken from this urn; therefore, All balls in this particular random sample are red. Peirce regarded the major premise here as being the Rule, the minor premise as being the particular Case, and the conclusion as being the Result of the argument. The argument is a piece of deduction (necessary inference): an argument from population to random sample.

Let us now see what happens if we form a new argument by interchanging the conclusion (the Result) with the major premise (the Rule). The resultant argument becomes: All S's are P's (Result); All S's are M's (Case); therefore, All M's are P's (Rule). This is the invalid syllogism AAA-3. But let us now regard it as pertaining to sampling theory. The argument becomes: All balls in this particular random sample are red; All balls in this particular random sample are taken from this urn; therefore, All balls in this urn are red. What we have here is an argument from sample to population, and this is what Peirce understood to be the core meaning of induction: argument from random sample to population.

Let us now go further and see what happens if, from the deduction AAA-1, we form a new argument by interchanging the conclusion (the Result) with the minor premise (the Case). The resultant argument becomes: All M's are P's (Rule); All S's are P's (Result); therefore, All S's are M's (Case). This is the invalid syllogism AAA-2. But let us now regard it as pertaining to sampling theory. The argument becomes: All balls in this urn are red; All balls in this particular random sample are red; therefore, All balls in this particular random sample are taken from this urn. What we have here is nothing at all like an argument from population to sample or an argument from sample to population: it is a form of probable argument entirely different from both deduction and induction. This new type of argument Peirce called abduction (also, retroduction, and also, hypothesis).

Over many years Peirce modified his views on the three types of arguments, sometimes changing his views but mostly just extending them. He seemed to have some hesitation, for example, about whether arguments from analogy were inductions (on properties of things) or abductions. The main extension of his earliest views involved integrating the argument forms into his view of the scientific method. In fact, his most mature position seemed almost to equate the three types of argument with three phases of the scientific method.

Pragmatism, Pragmaticism, and the Scientific

Method

Probably Peirce's best-known works are the first two articles in a series of six that were collectively entitled *Illustrations of the Logic of Science* and published in *Popular Science Monthly* in 1877 and 1878. The first is entitled "The Fixation of Belief" and the second is entitled "How to Make Our Ideas Clear." In the first Peirce defended, in a manner consistent with idealism, the superiority of the scientific method over other methods of overcoming doubt by "fixing belief." In the second Peirce defended the pragmatic/pragmaticistic notion of clear concepts.

Perhaps the single most important fact to keep in mind in understanding Peirce's philosophy is that Peirce was a practicing physical scientist all his life, and that as he understood them, philosophy and logic were themselves also sciences. Moreover, he understood philosophy to be the philosophy of science and logic to be the logic of science (where "science" has its broadest sense, which is best captured by the German word *Wissenschaft*).

It is in this light that his specifications of the nature of pragmatism (which he later called "pragmaticism" in order to distinguish his own scientific philosophy from other conceptions and theories that were trafficked under the title "pragmatism") are to be understood. When he said that the whole meaning of a (clear) conception consists in the entire set of its practical consequences, he had in mind that a meaningful conception must have some experiential "cash value," capable of being specified as some sort of collection of possible empirical observations under specifiable conditions. Peirce insisted that the entire meaning of a meaningful conception consisted in the totality of such specifications of possible observations. For example, Peirce tended to spell out the meaning of dispositional properties such as "hard" or "heavy" by using the same sort of counterfactual constructions that, say, Hempel would use. Peirce was not a simple operationalist or verificationist, but his views were akin to operationalism and verificationism.

The previous point is related to the fact that Peirce was always a philosopher who had broad and deep affinities with idealism. Indeed, having rejected a great deal in Kant, Peirce nevertheless shared with Kant the view that the *Ding an sich* plays no role in philosophy or science other than that of a *Grenzbegriff*, or, perhaps a bit more accuratedly, a limiting concept. The notion can play no direct role in the sciences; science can deal only with phenomena, and all concepts must somehow be traceable back to phenomenological roots. Toward the end of his life Peirce began to regard himself as a thinker somewhat akin to Hegel, one of the avowed philosophical enemies of his youth. Peirce's brand of idealism is of the Kantian "transcendental" sort; and, even when Peirce called himself or is called by others a "realist," it must be kept in mind that Peirce was always a realist of the Kantian "empirical" sort. His realism is similar to what Hilary Putnam has called "internal realism." (Peirce was also a realist in another sense: anti-nominalist. More on this is given below.)

From his earliest to his latest writings Peirce attacked all forms of epistemological foundationalism and in particular all form of Cartesianism. Philosophy must begin wherever it happens to be at the moment, he thought, and not at some ideal foundation, for example in private references. The only important thing

in thinking scientifically is applying the scientific method itself. This method he held to be essentially public and reproducible in its activities, as well as self-correcting in following sense: No matter where different researchers may begin, as long as they follow the scientific method, their results will eventually converge toward the same result. (The pragmatic conception of meaning implies that two theories with exactly the same empirical content must have, despite superficial appearances, the same meaning.) This ideal point of convergence is what Peirce means by "the truth," and "reality" is simply what is meant by "the truth." That these notions of reality and truth are inherently idealist rather than realist in nature should need no special pleading.

Connected with Peirce's anti-foundationalism is his insistence on the fallibility of particular achievements in science. Although the scientific method will eventually converge to something, nevertheless at any temporal point in inquiry we are only at a provisional stage of it and cannot ascertain how far off we may be from the limit to which we are somehow converging. This insistence on the fallibilism of human inquiry is connected with several other important ideas of Peirce's, such as his tychism, his evolutionism, and his anti-determinism. (These will be discussed below.) Despite Peirce's insistence on fallibilism, he is not an epistemological pessimist: indeed, quite the opposite: he tends to hold that every genuine question (that is, every question whose possible answers have empirical content) can be answered in principle, or at least should not be assumed to be unanswerable. For this reason, one his most important dicta is "Do not block the path of inquiry!"

Peirce described the scientific method as consisting of abduction, deduction, and induction, plus the economics of research. His understanding of the scientific method is not far different from the standard idea of the scientific method (which perhaps derives historically from William Whewell and Peirce) as being the method of constructing hypotheses, deriving consequences from these hypotheses, and then experimentally testing these hypotheses. (The main Peircean factor left out is Peirce's notion of the economics of research.) Conversely, he increasingly came to understand the three types of inference as being the stages of the scientific method. For example, as Peirce came to extend and generalize his notion of abduction, abduction became defined as inference to and provisional acceptance of an explanatory hypothesis for the purposes of testing it. Abduction is not always inference to the best explanation, but it is always inference to some explanation or at least to something that clarifies or makes routine some information that has previously been "surprising," in the sense that we would not have routinely expected it, given our then-current state of knowledge. Deduction came to mean for Peirce the drawing of conclusions as to what observable phenomena should be expected if the hypothesis is correct. Induction came for him to mean the entire process of experimentation performed in service of hypothesis testing.

Peirce's idea of the economy (or: the economics) of research is an ineliminable part of his idea of the scientific method. He understood that science always operates in some given historical and socio-economic context, in which context certain problems are paramount and other problems trivial or frivolous. He understood that in such a context some experiments may be crucial and others insignificant. He understood that the economic resources of the scientist are severely limited, while the "great ocean of truth" that lies undiscovered before us is infinite. Research resources, such as personnel, time, and apparatus, are costly; and it is irrational to squander them. He proposed, therefore, that careful

consideration be paid to the problem of how to obtain the biggest epistemological "bang for the buck." In effect, the economics of research is akin to a cost/benefit analysis in connection with states of knowledge. Although this idea has been only little explored by Peirce scholars, Peirce himself regarded it as central to the scientific method and to the idea of rational behavior. It is connected with what he called "speculative rhetoric" or "methodeutic" (which will be discussed below).

Anti-determinism, Tychism, and Evolutionism

Against powerful currents of determinism that derived from the Enlightenment philosophy of the eighteenth century, Peirce urged that there was not the slightest scientific evidence for determinism and that there was considerable scientific evidence against it. Always by the words "science" and "scientific" Peirce understood reference to actual practice by scientists in the laboratory and the field, and not reference to entries in scientific textbooks. In attacking determinism, therefore, Peirce appealed to the evidence of the actual phenomena in laboratories and fields. Here, what is obtained as the actual observations (e.g. measurements) does not conform to some exact point or smooth function. For example, if we take, however carefully we may do so, a thousand measurements of some physical quantity, we will not obtain a thousand equal results, but rather only a distribution (usually a normal or Gaussian distribution of hundreds) of different results. Again, if we measure the value of an independent variable that we assume to depend on some given parameter, and if we let the parameter vary while we take successive measurements, the result will never be a smooth function (for example, a straight line or an ellipse); rather it will be a "jagged" result, to which we can at best *fit* a smooth function by using some clever method (for example, least-squares fitting). Moreover, the variation and inexactness of measurements become, Peirce maintained, the more pronounced and obtrusive the more refined and microscopic are our measurements. (Obviously, Peirce would not have been the least surprised by the results of measurements at the quantum level.)

What the facts of scientific practice tell us, then, is that, although the universe displays varying degrees of *habit*, that is to say of partial, varying, approximate, and statistical regularity, the universe does not display deterministic *law*, that is to say total, exact, non-statistical regularity. Moreover, the habits that nature displays appear in varying degrees of entrenchment: from the almost pure freedom and spontaneity of some processes of thought, at one end of the spectrum, to the nearly law-like behavior of large physical objects like planets, at the other end of the spectrum.

Science shows, then, that not everything is fixed by exact law (even if everything should be constrained to some extent by habit) and that spontaneity has an objective place in the universe. Peirce called this doctrine "tychism," a word taken from the Greek word for "chance" or "luck" or "what the gods choose to lay on one." Tychism is a fundamental part of Peirce's view, and reference to his tychism provides an added reason for Peirce's insisting on the irreducible fallibilism of inquiry. For nature is not a static world of law but rather a dynamic world that manifests considerable spontaneity. (Peirce would have regarded the irreducibility of quantum mechanics to some "hidden-variables" theory as being a mere matter of course.)

Three figures from the history of culture loomed exceedingly large in the intellectual atmosphere of the period in which Peirce was most active: Hegel in philosophy, Lyell in geology, and Darwin (along with Watson) in biology. These thinkers have a single theme in common: evolution. Hegel described an evolution of ideas, Lyell an evolution of geological structures, and Darwin an evolution of biological species and varieties. Peirce's thinking is deeply permeated with the evolutionary idea, which he extended beyond the confines of any particular subject matter. For Peirce, the entire universe is an evolutionary product; indeed, he conceived that even the most firmly entrenched of nature's habits (for example, even those habits typically called "natural laws") have themselves evolved, and accordingly should be subjects of inquiry. One can sensibly seek evolutionary explanations of the existence of particular natural laws.

One possible path along which nature acquires its habits was explored by Peirce using statistical analysis in situations of non-Bernoullian trials. Peirce showed that, if we posit a primal habit in nature, viz. the tendency however slight to take on habits, then the result is often a high degree of regularity in the long run. For this reason, Peirce suggested that in the remote past nature was considerably more spontaneous than it later became, and that in general the habits nature has come to exhibit have evolved, just like ideas, geological formations, and biological species have evolved.

In this evolutionary notion of nature and natural law we have an additional support of Peirce's insistence on the inherent fallibilism of scientific inquiry. Nature may simply change sometimes, even in its most entrenched fundamentals. Thus, even if scientists were at one point in time to have accurate conceptions about nature, this fact would not ensure that at some later point in time these same concpetions would remain accurate.

An especially intriguing and curious twist that Peirce's evolutionism takes is what is called its "agapeism." According to Peirce, the most fundamental engine of the evolutionary process is not struggle, strife, greed, or competition. Rather it is nurturing love, in which an entity is prepared to sacrifice its own perfection for the sake of the wellbeing of its neighbor. This doctrine had both a social significance for Peirce, who apparently had the intention of arguing against the popular socio-economic Darwinism of the late nineteenth century, and a cosmic significance, which Peirce associated with the doctrine of the Gospel of John and with the mystical ideas of Swedenborg and Henry James. Peirce even argued that logicality in some sense presupposes the ethics of self-sacrifice.

Synechism, the Continuum, Infinites, and Infinitesimals

Peirce was the first scientific thinker, or at least one of the first scientific thinkers, to argue in favor of the actual existence of infinite sets. His criterion of the difference between finite and infinite sets was that the so-called "syllogism of transposed quantity" introduced by de Morgan applied only to finite sets and not to infinite ones. The syllogism of transposed quantity runs as follows. We have a binary relation *R* defined on a set *S*, such that the relation satisfies the following two properties (where the quantifications

are taken over the set *S*). For all *x* there is a *y* such that *Rxy*. And for all *x*, *y*, *z*, *Rxz* and *Ryz* implies that $x = y$. The conclusion (of the syllogism of transposed quantity) is that for all *x* there exists a *y* such that *Ryx*. One of Peirce's favorite examples helps elucidate the idea, even if it perhaps be not perfectly politically correct: Every Texan kills some Texan; no Texan is killed by more than one Texan; therefore every Texan is killed by some Texan. The argument's conclusion follows only if the set of Texans is finite.

If for the relation *R* in question we take $f(x) = y$, where the function is defined on and has values in the set *S*, we can easily see that the syllogism of transposed quantity then says that no one-one function can map a set to a proper subset of itself. This assertion holds, of course, only for finite sets. So, as it turns out, Peirce's definition of the difference between finite and infinite sets is (pretty close to) equivalent to the standard one.

Peirce held that the continuity of space, time, ideation, feeling, and perception is an irreducible deliverance of science, and that an adequate conception of the continuous is an extremely important part of all the sciences. This doctrine he called "synechism," a word deriving from the Greek preposition that means "(together) with." In mid-1892, somewhat under the influence of reading Cantor's works, Peirce defined a (linear) continuum to be a linearly-ordered infinite set *C* such that (1) for any two distinct members of *C* there exists a third member of *C* that is strictly between these; and (2) every countably infinite subset of *C* that has an upper (lower) bound in *C* has a least upper bound (greatest lower bound) in *C*. The first property he called "Kanticity" and the second "Aristotelicity." (Today we would likely call these properties "density" and "closedness," respectively.) The second condition has the corollary that a continuum contains all its limit points, and sometimes Peirce used this property in conjunction with "Kanticity" to define a continuum. Toward the end of the nineteenth century Peirce remarked that he had framed an updated conception of continua by loosening his attachment to Cantor's ideas, but what this new approach is has not yet been explored by Peirce scholars.

Not only did Peirce defend infinite magnitudes, but also he defended infinitesimal magnitudes. Moreover, he argued for the consistency of introducing infinitesimals into the number system, and he wanted to use infinitesimals to justify the traditional pre-Gaussian definitions and underpinnings of the differential calculus. He also made a number of remarks that suggest that, in connection with the foregoing enterprise, he had a novel conception of the topology of the real numbers. All these remarks he connected with his notion of the continuum and his previous defenses of infinite sets. For these reasons some Peirce scholars have suggested that his ideas were an anticipation of Abraham Robinson's non-standard analysis. Whether this be so or not is, however, at the present time far from clear: so far no commentator has provided anything close to being a careful and detailed exposition of this point, and most of Peirce's published writing on this topic is extremely obscure. The entire analysis of Peirce's notion of an infinitesimal, as well as the exact bearing this notion has on his concept of continuity and on his idea of the topology of the real numbers, still awaits meticulous mathematical discussion.

Theory of Probability

In light of Peirce's tychism and his view that statistical information is often the most exact information we can have about phenomena, it should not be surprising that Peirce devoted close attention to probability theory and statistical analysis. Indeed, Peirce not only extensively used the concept of probability but also offered a pragmatistic account of the notion of probability itself.

Peirce vigorously attacked the view of de Morgan that probability was a measure of our confidence or degree of belief: a view known today as the subjectivist theory of probability. Along with this attack, Peirce ridiculed various Bayesian-type analyses of the problem of induction (for example, the work of Quételet), on the grounds that the relevant Bayesian "prior probabilities" cannot be assigned unless one first assumes a subjectivist view and thus equates complete lack of information about something with that something's having a probability of 1/2, which equation is an egregious error in Peirce's estimation.

Rather than holding probability to be a measure of degree of confidence or belief, Peirce adopted an objectivist notion of probability that he likened to the doctrine of John Venn. Indeed, he held that probability is actually a notion with clear empirical content and clear empirical procedures for ascertaining that content, as follows. First, what is assigned a probability, insofar as the notion is used scientifically, is neither a proposition nor an event nor a type of event. Rather, what is assigned a probability is an argument, with premisses (Peirce insisted on this spelling rather than the spelling "premises") and a conclusion. Second, in order to ascertain the probability of a particular argument, the observer notes all occasions on which all of its premisses are true, case by case, just as they come under observation. For each of these occasions the observer notes whether the conclusion is true or not. The observer keeps an ongoing ratio whose numerator is the number of occasions so far observed on which the conclusion as well as the premisses are true and whose denominator is the number of occasions so far observed on which simply the premisses are true (irrespective of whether the conclusion is also true). At each observation the observer computes this ratio, which then encompasses all the observer's past observations of occasions on which the premisses are true. The probability of the argument in question is defined by Peirce to be the limit of the crucial ratio as the number of observations tends to grow infinitely large (if this limit exists).

It might be thought that, when Peirce adopted the view of objective spontaneity and more or less entrenched objective habit in the universe (tychism), he perforce gave up the foregoing account of probability. Such a thought, however, would be a mistake; it rests failing to realize that objective attributions of probability for Peirce are consequent upon rather than inconsistent with his commitment to the pragmatistic account of probability that was given above.

Psycho-physical Monism and Anti-nominalism

Peirce held that science suggests that the universe has evolved from a condition of maximum freedom and spontaneity into its present condition, in which it has taken on a number of more and less entrenched habits. With pure freedom and spontaneity Peirce tended to associate mind, and with entrenched habits he tended to associate matter (or, more generally, the physical). Thus he tended to see the universe as the end-product-so-far of a process in which mind has acquired habits and has "congealed" (this is the very

word Peirce used) into matter.

This notion of all things as being evolved psycho-physical unities of some sort places Peirce well within the sphere of what might be called "the grand old-fashioned metaphysicians," along with such thinkers as Plato, Aristotle, Aquinas, Spinoza, Leibnitz, Hegel, Schopenhauer, Whitehead, *et al.* Some contemporary philosophers might be inclined to reject Peirce out of hand upon discovering this fact. Others might find his notion of psycho-physical unities not so offputting or indeed even attractive. What is crucial is that Peirce argued that mind pervades all of nature in varying degrees, and is not found merely in its most advanced animal species.

This pan-psychistic view, combined with synechism, meant for Peirce that mind is extended in some sort of continuum throughout the universe. Peirce tended to think of ideas as existing in mind in somewhat the same way as physical forms exist in physically extended things, and he even spoke of ideas as "spreading" out through the same continuum in which mind is extended. This set of conceptions is part of what Peirce regarded as (his version of) Scotistic realism, which he opposed to nominalism. He tended to blame what he regarded as the errors of much of the philosophy of his contemporaries as owing to the nominalistic disregard for the objective existence of form.

Triadism and the Universal Categories

Merely to say that Peirce was extremely fond of placing things into groups of three, of trichotomies, and of triadic relations, would fail miserably to do justice to the overwhelming obtrusiveness in his philosophy of the number three. Indeed, he made the most fundamental categories of all "things" of any sort whatsoever the categories of "Firstness," "Secondness," and "Thirdness," and he often described "things" as being "firsts" or "seconds" or "thirds." For example, with regard to the trichotomy "possibility," "actuality," and "necessity," possibility he called a first, actuality he called a second, and necessity he called a third. Again: quality was a first, fact was a second, and habit (or rule or law) was a third. Again: entity was a first, relation was a second, and representation was a third. Again: rheme (by which Peirce meant a relation of arbitrary adicity or arity) was a first, proposition was a second, and argument was a third. The list goes on and on. Let us refer to Peirce's penchant for describing things in terms of trichotomies and triadic realtions as Peirce's "triadism."

If Peirce had a general rationale for his triadism, Peirce scholars have not yet made it clear what this rationale might be. He seemed to base his triadism on what he called "phaneroscopy," by which word he meant the mere observation of phenomenal appearances. He regularly commented that the phenomena just *do* fall into three groups and that they just *do* display irreducibly triadic relations.

Although there are many examples of phenomena that do seem more or less naturally to divide into three groups, Peirce seems to have been driven by something more than mere examples in his insistence on applying his categories to almost everything imaginable. Perhaps it was the influence of Kant, whose twelve categories divide into four groups of three each. Perhaps it was the triadic structure of the stages of thought as described by Hegel, or even the triune commitments of orthodox Christianity (to which

Peirce seemed to subscribe). Certainly involved was Peirce's commitment to the ineliminability of mind in nature, for Peirce closely associated the activities of mind with a particular triadic relation that he called the "sign" relation. (More on this topic appears below.) Also involved was Peirce's so-called "reduction thesis" in logic (on which more will given below), to which Peirce had concluded as early as 1870.

It is difficult to imagine even the most fervently devout of the passionate admirers of Peirce, of which there are many, saying that his account (or, more accurately, his various accounts) of the three universal categories is (or are) clear and compelling. Yet, in almost everything Peirce wrote from the time the categories were first introduced, they found a place. Their analysis and an account of their general rationale, if there be such, constitute chief problems in Peirce scholarship.

Mind and Semeiotic

Connected with Peirce's insistence on the ubiquity of mind in the cosmos is the importance he attached to what he called "semeiotic," the theory of signs in the most general sense. Peircean semeiotic is almost totally different what has come to be called "semiotics," and which hales not so much from Peirce as from Saussure and Charles W. Morris. Peircean semeiotic derives ultimately from the theory of signs of Duns Scotus and its later development by John of St. Thomas (John Poirot). In Peirce's theory the sign relation is a triadic relation, a special species of the genus: the representing relation. Whenever the representing relation has an instance, we find one thing (the "object") being represented by another thing (the "representamen") to (or: in) a third thing (the "interpretant"), and represented in such a way that the interpretant is thereby determined to be also a representamen of the object to yet another interpretant in the representation relation. Obviously, Peirce's definition entails that we have an infinite sequence of representamens of an object whenever we have any one representamen.

The sign relation is the representing relation whenever the first interpretant (and consequently each member of the whole infinite sequence of interpretants) is a cognition of a mind. In any instance of the sign relation an object is signified by a sign to a mind. One of Peirce's central tasks was that of analyzing all possible kinds of signs.

Semeiotic and Logic

Peirce's settled opinion was that logic in the broadest sense is to be equated with semeiotic, and that logic in a much narrower sense (which he typically called "logical critic") is one of three major divisions or parts of semeiotic. Thus, in his later writings, he divided semeiotic into speculative grammar, logical critic, and speculative rhetoric (also called "methodeutic"). Peirce's word "speculative" is his Latinate version of the Greek-derived word "theoretical," and should be understood to mean exactly the word "theoretical." Peirce's tripartite division of semeiotic is not to be confused with Charles W. Morris's division: syntax, semantics, and pragmatics (although there may be some commonalities in the two trichotomies).

By speculative grammar Peirce understood the analysis of the kinds of signs there are and the ways that they can be combined significantly. For example, under this heading he introduced three trichotomies of signs and argued for the real possibility of only certain kinds of signs. Signs are qualisigns, sinsigns, or legisigns, accordingly as they are mere qualities, individual events and states, or habits (or laws), respectively. Signs are icons, indices (also called "semes"), or symbols (sometimes called "tokens"), accordingly as they derive their significance from resemblance to their objects, a real relation (for example, of causation) with their objects, or are connected only by convention to their objects, respectively. Signs are rhematic signs (also called "sumisigns" and "rhemes"), dicisigns (also called "quasi-propositions"), or arguments (also called "suadisigns"), accordingly as they are predicational/relational in character, propositional in character, or argumentative in character. Because the three trichotomies are orthogonal to each other, together they yield the abstract possibility that there are 27 distinct kinds of signs. Peirce argued, however, that 17 of these are logically impossible, so that finally only 10 kinds of signs are genuinely possible. In terms of these 10 kinds of signs, Peirce endeavored to construct a theory of all possible natural and conventional signs, whether simple or complex.

What Peirce meant by "logical critic" is pretty much logic in the ordinary, accepted sense of "logic" from Aristotle's logic to present-day mathematical logic. As might be expected, a crucial concern of logical critic is to characterize the difference between correct and incorrect reasoning. Some of Peirce's accomplishments in this area will be discussed below.

By "speculative rhetoric" or "methodeutic" Peirce understood all inquiry into the principles of the effective use of signs for producing valuable courses of research and giving valuable expositions. Methodeutic studies the methods that researchers should use in investigating, giving expositions of, and creating applications of the truth. This idea may overlap to some small extent Morris's notion of "pragmatics," but the spirit of Peirce's notion is much wider than that of Morris's. Moreover, Peirce handled the notion of indexical reference under the heading of speculative grammar and not speculative rhetoric, whereas the topic certainly belongs to Morris's pragmatics. So far as is known, Peirce did not develop details of the topic of speculative rhetoric to any great extent, but it is clear that the important topic of the economy of research is closely affiliated with it.

The Classification of the Sciences

Peirce maintained an interest in the topic of classification or taxonomy in general, and he considered biology and geology the foremost sciences to have made progress in developing genuinely useful classifications of things. In his own theory of classification, he seemed to regard some sort of cluster analysis as holding the key to creating really useful classifications. He regularly strove to create a classification of all the sciences that would be as useful to logic as the systems of the biologists and geologists were to these scientists.

As with many of Peirce's divisions, his classification of the sciences is a taxonomy consisting of triads.

For example he classifies all the sciences into those of discovery, review, and practicality. Sciences of discovery he divides into mathematics, philosophy, and what he calls "idioscopy" (by which he seems to mean the class of all the particular or special sciences like physics, psychology, and so forth). Mathematics he divides into mathematics of logic, of discrete series, and of continua and pseudo-continua. Philosphy divides into phenomenology, normative science, and metaphysics. Normative science divides into aesthetics, ethics, and logic. And so on and on. Occasionally there is found a division into two: for example, he divides idioscopy into the physical sciences and the psychical (or human) sciences. But mostly the division is into threes.

Peirce scholars have found the topic of Peirce's classification of the sciences a fertile ground for assertions about what is most basic in all thinking, in Peirce's view. Whether or not such assertions run afoul of Peirce's anti-foundationalism is itself a topic for further study.

Logic

In the extensiveness and originality of his contributions to mathematical logic, Peirce is almost without equal. His writings and original ideas are so numerous that there is no way to do them justice in a small article such as the present one. Accordingly, only a few of his achievements will be mentioned here.

Peirce's special strength lay not so much in theorem-proving as rather in the invention and developmental elaboration of novel systems of logical syntax and fundamental logical concepts. He invented dozens of different systems of logical syntax, including a syntax based on a generalization of de Morgan's relative product operation, an algebraic syntax that mirrored Boolean algebra to some extent, a quantifier-and-variable syntax that (except for specific symbols) is identical to the much later Russell-Whitehead syntax, and even two systems of two-dimensional syntax: the entitative graphs and the existential graphs, the latter being a syntax for logic using the mathematical apparatus of topological graph theory.

In 1870 Peirce published a long paper "Description of a Notation for the Logic of Relatives" in which he introduced for the first time in history, two years before Frege's *Begriffschrift* a complete syntax for the logic of relations of arbitrary adicity (or arity). In this paper the notion of the variable (though not under the name "variable") was invented, and Peirce provided devices for negating, combining relations, and quantifying. By 1883, along with his student O. H. Mitchell, he had developed a full syntax for quantificational logic, only a little different in specific symbols (as was mentioned just above) from the standard Russell-Whitehed syntax that did not appear until 1910.

Peirce introduced the material-conditional operator into logic, developed the Shaffer stroke and daggar operators 40 years before Shaffer, and developed a full logical system based only on the stroke function. As Garret Birkhoff notes in his *Lattice Theory* it was in fact Peirce who invented the concept of a lattice (around 1883). (Quite possibly, it is Peirce's lattice theory that holds the key to his technical theory of infinitesimals and the continuum.)

During his years teaching at Johns Hopkins University, Peirce began to research the four-color map conjecture and developed extensive connections between logic and topology, especially topological graph theory. Ultimately these researches bore fruit in his existential graphs, but probably his writings in this area contain a considerable number of other valuable ideas and results. He hinted that he had made great progress in the theory of provability and unprovability by exploring the connections between logic and topology.

Peirce's Reduction Thesis

Peirce's so-called "Reduction Thesis" is the thesis that all relations of arbitrary adicity may be constructed from triadic relations alone, whereas monadic and dyadic relations alone are not sufficient to allow the construction of even a single "non-degenerate" (that is: non-Cartesian-factorable) triadic relation. Although the germ of his argument for the Reduction Thesis lay in his 1870 paper "Description of a Notation for the Logic of Relatives," the Thesis was for over a century doubted by many, especially after the publication of a proof by Willard Van Orman Quine that all relations could be constructed exclusively from dyadic ones. As it turns out, both Peirce and Quine were correct: the issue all depends on exactly what constructive resources are to be allowed to be used in building relations out of other relations. (Obviously, the more extensive and powerful are the constructive resources, the more likely it is that all relations can be constructed from dyadic ones alone by using them.) An exact exposition and proof of Peirce's Reduction Thesis was finally accomplished in 1988, and it makes clear that Peirce's constructive resources are to be understood to include only negation, a generalization of de Morgan's relative product operation, and the use of a particular triadic relation that Peirce called "the teridentity relation" and that we might today write as $x = y = z$.

Peirce felt that the teridentity relation was in some way much more fundamental than the usual dyadic identity relation $x = y$. He also felt that relative product was a much more fundamental operation than, say, Boolean product or Boolean sum. The full philosophical import of his Reduction Thesis, and the philosophical importance of his triadism insofar as this triadism rests on his Reduction Thesis, cannot be ascertained without a prior understanding of his theory of identity and his view of the nature of the relative product operation.

Contemporary Practical Applications of Peirce's Ideas

Currently, considerable interest is being taken in Peirce's ideas from outside the arena of academic philosophy. The interest comes from industry, business, technology, and the military; and it has resulted in the existence of a number of agencies, institutes, and laboratories in which ongoing research into and development of Peircean concepts is being undertaken.

This interest has arisen, apparently, in two ways. First, some two decades agao in the former Soviet

Union interest in Peirce and Karl Popper led logicians and computer scientists like Victor Finn and Dmitri Pospelov to try to find ways in which computer programs could generate Peircean hypotheses (Popperian "conjectures") in semeiotic contexts (non-numerical contexts). Under the guide in particular of Finn's intelligent systems laboratory in VINITI-RAN (the All-Russian Institute of Scientific and Technical Information of the Russian Academy of Sciences), elaborate techniques for automatic generation of hypotheses have been found and extensively utilized for many practical purposes. Among these are sociological prediction, pharmacological discovery, and the analysis of processes of industrial production. Interest in Finn's work, and through it the practical application of Peirce's philosophy, has spread to France, Germany, Denmark, and ultimately the United States.

Second, as the limits of expert systems in artificial intelligence contexts have become increasingly clear to computer scientists, they have begun to search for methods beyond those of the production rules of expert systems. One promising line of research has been in automating Peirce's concept of the scientific method, complete with techniques for hypothesis-generation and making assessments of the costs and benefits of exploring hypotheses. In some areas of research added impetus has been provided by the similarity of Peircean techniques to techniques that have already proven useful. For example, in the field of automated multi-track radar, the similarity of Peircean scientific method to the so-called "Kalman filter" has been noted by many systems analysts. Again, those interested in military command-and-control often note the similarity of Peircean scientific method to the classic OODA loop ("observe, orient, decide, act") of comand-and-control-theory. The areospace industry, especially in France and the United States, is currently investigating Peircean ideas in connection with avionics systems that monitor aircraft "health."

Such practical applications of Peircean ideas may seem surprising to many philosophers, but they surely would not have surprised Peirce. Indeed, given his lifelong goals as a scientist-philosopher, he probably would have found the current situation entirely in accord with his expectations.

Aristotle's Logic

Aristotle's logic, especially his theory of the syllogism, has had an unparalleled influence on the history of Western thought. It did not always hold this position: in the Hellenistic period, Stoic logic, and in particular the work of Chrysippus, was much more celebrated. However, in later antiquity, following the work of Aristotelian Commentators, Aristotle's logic became dominant, and Aristotelian logic was what was transmitted to the Arabic and the Latin medieval traditions, while the works of Chrysippus have not survived.

This unique historical position has not always contributed to the understanding of Aristotle's logical works. Kant thought that Aristotle had discovered everything there was to know about logic, and the historian of logic Prantl drew the corollary that any logician after Aristotle who said anything new was confused, stupid, or perverse. During the rise of modern formal logic following Frege and Peirce, adherents of Traditional Logic (seen as the descendant of Aristotelian Logic) and the new mathematical logic tended to see one another as rivals, with incompatible notions of logic. More recent scholarship has often applied the very techniques of mathematical logic to Aristotle's theories, revealing (in the opinion of many) a number of similarities of approach and interest between Aristotle and modern logicians.

This article is written from the latter perspective. As such, it is about Aristotle's logic, which is not always the same thing as what has been called "Aristotelian" logic.

---

§1: Introduction

Aristotle's logical works contain the earliest formal study of logic that we have. It is therefore all the more remarkable that together they comprise a highly developed logical theory, one that was able to command immense respect for many centuries: Kant, who was ten times more distant from Aristotle than we are from him, even held that nothing significant had been added to Aristotle's views in the intervening two millennia.

In the last century, Aristotle's reputation as a logician has undergone two remarkable reversals. The rise of modern formal logic following the work of Frege and Russell brought with it a recognition of the many serious limitations of Aristotle's logic; today, very few would try to maintain that it is adequate as a basis for understanding science, mathematics, or even everyday reasoning. At the same time, scholars trained in modern formal techniques have come to view Aristotle with new respect, not so much for the correctness of his results as for the remarkable similarity in spirit between much of his work and modern logic. As Jonathan Lear has put it, "Aristotle shares with modern logicians a fundamental interest in metatheory": his primary goal is not to offer a practical guide to argumentation but to study the properties of inferential systems themselves.

§2: Aristotle's Logical Works: The *Organon*

The ancient commentators grouped together several of Aristotle's treatises under the title *Organon* ("Instrument") and regarded them as comprising his logical works:

1. *Categories*
2. *On Interpretation*
3. *Prior Analytics*
4. *Posterior Analytics*
5. *Topics*
6. *On Sophistical Refutations*

In fact, the title *Organon* reflects a much later controversy about whether logic is a part of philosophy (as the Stoics maintained) or merely a tool used by philosophy (as the later Peripatetics thought); calling the logical works "The Instrument" is a way of taking sides on this point. Aristotle himself never uses this term, nor does he give much indication that these particular treatises form some kind of group, though there are frequent cross-references between the *Topics* and the *Analytics*. On the other hand, Aristotle

treats the *Prior* and *Posterior Analytics* as one work, and *On Sophistical Refutations* is a final section, or an appendix, to the *Topics*). To these works should be added the *Rhetoric*, which explicitly declares its reliance on the *Topics*.

§3: The Subject of Logic: "Syllogisms"

All Aristotle's logic revolves around one notion: the **deduction** (*sullogismos*). A thorough explanation of what a deduction is, and what they are composed of, will necessarily lead us through the whole of his theory. What, then, is a deduction? Aristotle says:

> A deduction is speech (*logos*) in which, certain things having been supposed, something different from those supposed results of necessity because of their being so. (*Prior Analytics* I.2, 24b18-20)

Each of the "things supposed" is a **premise** (*protasis*) of the argument, and what "results of necessity" is the **conclusion** (*sumperasma*).

The core of this definition is the notion of "resulting of necessity" (*ex anankês sumbainein*). This corresponds to a modern notion of logical consequence: X results of necessity from Y and Z if it would be impossible for X to be false when Y and Z are true. We could therefore take this to be a general definition of "valid argument".

A. Induction and Deduction

Deductions are one of two species of argument recognized by Aristotle. The other species is **induction** (*epagôgê*). He has far less to say about this than deduction, doing little more than characterize it as "argument from the particular to the universal". However, induction (or something very much like it) plays a crucial role in the theory of scientific knowledge in the *Posterior Analytics*: it is induction, or at any rate a cognitive process that moves from particulars to their generalizations, that is the basis of knowledge of the indemonstrable first principles of sciences.

B. Aristotelian Deductions and Modern Valid Arguments

Despite its wide generality, Aristotle's definition of deduction is not a precise match for a modern definition of validity. Some of the differences may have important consequences:

1. Aristotle explicitly says that what results of necessity must be different from what is supposed. This would rule out arguments in which the conclusion is identical to one of the premises. Modern notions of validity regard such arguments as valid, though trivially so.
2. The plural "certain things having been supposed" was taken by some ancient commentators to rule out arguments with only one premise.

3. The force of the qualification "because of their being so" has sometimes been seen as ruling out arguments in which the conclusion is not ‘relevant’ to the premises, e.g., arguments in which the premises are inconsistent, arguments with conclusions that would follow from any premises whatsoever, or arguments with superfluous premises.

Of these three possible restrictions, the most interesting would be the third. This could be (and has been) interpreted as committing Aristotle to something like a relevance logic. In fact, there are passages that appear to confirm this. However, this is too complex a matter to discuss here.

However the definition is interpreted, it is clear that Aristotle does not mean to restrict it only to a subset of the valid arguments. This is why I have translated *sullogismos* with ‘deduction’ rather than its English cognate. In modern usage, ‘syllogism’ means an argument of a very specific form. Moreover, modern usage distinguishes between valid syllogisms (the conclusions of which follow from their premises) and invalid syllogisms (the conclusions of which do not follow from their premises). The second of these is inconsistent with Aristotle's use: since he defines a *sullogismos* as an argument in which the conclusion results of necessity from the premises, "invalid *sullogismos*" is a contradiction in terms. The first is also at least highly misleading, since Aristotle does not appear to think that the *sullogismoi* are simply an interesting subset of the valid arguments. Moreover (see below), Aristotle expends great efforts to argue that every valid argument, in a broad sense, can be "reduced" to an argument, or series of arguments, in something like one of the forms traditionally called a syllogism. If we translate *sullogismos* as "syllogism, ", this becomes the trivial claim "Every syllogism is a syllogism",

§4: Premises: The Structures of Assertions

Syllogisms are structures of sentences each of which can meaningfully be called true or false: **assertions** (*apophanseis*), in Aristotle's terminology. According to Aristotle, every such sentence must have the same structure: it must contain a **subject** (*hupokeimenon*) and a **predicate** and must either affirm or deny the predicate of the subject. Thus, every assertion is either the **affirmation** *kataphasis* or the **denial** (*apophasis*) of a single predicate of a single subject.

In *On Interpretation*, Aristotle argues that a single assertion must always either affirm or deny a single predicate of a single subject. Thus, he does not recognize sentential compounds, such as conjunctions and disjunctions, as single assertions. This appears to be a deliberate choice on his part: he argues, for instance, that a conjunction is simply a collection of assertions, with no more intrinsic unity than the sequence of sentences in a lengthy account (e.g. the entire *Iliad*, to take Aristotle's own example). Since he also treats denials as one of the two basic species of assertion, he does not view negations as sentential compounds. His treatment of conditional sentences and disjunctions is more difficult to appraise, but it is at any rate clear that Aristotle made no efforts to develop a sentential logic. Some of the consequences of this for his theory of demonstration are important.

A. Terms

Subjects and predicates of assertions are **terms**. A term (*horos*) can be either individual, e.g. *Socrates*, *Plato* or universal, e.g. *human*, *horse*, *animal*, *white*. Subjects may be either individual or universal, but predicates can only be universals: *Socrates is human*, *Plato is not a horse*, *horses are animals*, *humans are not horses*.

The word **universal** (*katholou*)appears to be an Aristotelian coinage. Literally, it means "of a whole"; its opposite is therefore "of a particular" (*kath' hekaston*). Universal terms are those which can properly serve as predicates, while particular terms are those which cannot.

This distinction is not simply a matter of grammatical function. We can readily enough construct a sentence with "Socrates" as its grammatical predicate: "The person sitting down is Socrates". Aristotle, however, does not consider this a genuine predication. He calls it instead a merely **accidental** or **incidental** (*kata sumbebêkos*) predication. Such sentences are, for him, dependent for their truth values on other genuine predications (in this case, "Socrates is sitting down").

Consequently, predication for Aristotle is as much a matter of metaphysics as a matter of grammar. The reason that the term *Socrates* is an individual term and not a universal is that the entity which it designates is an individual, not a universal. What makes *white* and *human* universal terms is that they designate universals.

Further discussion of these issues can be found in the entry on Aristotle's metaphysics.

B. Affirmations, Denials, and Contradictions

Aristotle takes some pains in *On Interpretation* to argue that to every affirmation there corresponds exactly one denial such that that denial denies exactly what that affirmation affirms. The pair consisting of an affirmation and its corresponding denial is a **contradiction** (*antiphasis*). In general, Aristotle holds, exactly one member of any contradiction is true and one false: they cannot both be true, and they cannot both be false. However, he appears to make an exception for propositions about future events, though interpreters have debated extensively what this exception might be (see further discussion below). The principle that contradictories cannot both be true has fundamental importance in Aristotle's metaphysics (see further discussion below).

C. All, Some, and None

One major difference between Aristotle's understanding of predication and modern (i.e. post-Fregean) logic is that Aristotle treats individual predications and general predications as similar in logical form: he gives the same analysis to "Socrates is an animal" and "Humans are animals". However, he notes that when the subject is a universal, predication takes on two forms: it can be either **universal** or **particular**. These expressions are parallel to those with which Aristotle distinguishes universal and particular terms, and Aristotle is aware of that, explicitly distinguishing between a term being a universal and a term being

universally predicated of another.

Whatever is affirmed or denied of a universal subject may be affirmed or denied of it it **universally** (*katholou* or "of all", *kata pantos*), **in part** (*kata meros*, *en merei*). or **indefinitely** (*adihoristos*).

	Affirmations		**Denials**	
Universal	P affirmed of all of S	Every S is P, All S is (are) P	P denied of all of S	No S is P
Particular	P affirmed of some of S	Some S is (are) P	P denied of some of S	Some S is not P, Not every S is P
Indefinite	P affirmed of S	S is P	P denied of S	S is not P

The "Square of Opposition"

In *On Interpretation,* Aristotle spells out the relationships of contradiction for sentences with universal subjects as follows:

	Affirmation	**Denial**
Universal	Every A is B	No A is B
Universal	Some A is B	Not every A is B

Simple as it appears, this table raises important difficulties of interpretation (for a thorough discussion, see the entry on the Square of Opposition).

In the *Prior Analytics*, Aristotle adopts a somewhat artificial way of expressing predications: instead of saying "X is predicated of Y" he says "Y belongs (*huparchei*) to X". This should really be regarded as a technical expression. The verb *huparchein* usually means either "begin" or "exist, be present", and Aristotle's usage appears to be a development of this latter use.

Some Convenient Abbreviations

For clarity and brevity, I will use the following semi-traditional abbreviations for Aristotelian categorical sentences (note that the predicate term comes *first* and the subject term *second*):

Abbreviation	**Sentence**
Aab	a belongs to all b (Every b is a)
Eab	a belongs to no b (No b is a)
Iab	a belongs to some b (Some b is a)
Oab	a does not belong to all b (Some b is not a)

§5: The Syllogistic

Aristotle's most famous achievement as logician is his theory of inference, traditionally called the **syllogistic** (though not by Aristotle). That theory is in fact the theory of inferences of a very specific sort: inferences with two premises, each of which is a categorical sentence, having exactly one term in common, and having as conclusion a categorical sentence the terms of which are just those two terms not shared by the premises. Aristotle calls the term shared by the premises the **middle term** (*meson*) and each of the other two terms in the premises an **extreme** (*akron*). The middle term must be either subject or predicate of each premise, and this can occur in three ways: the middle term can be the subject of one premise and the predicate of the other, the predicate of both premises, or the subject of both premises. Aristotle refers to these term arrangements as **figures** (*schêmata*):

A. The Figures

	First Figure		**Second Figure**		**Third Figure**	
	Predicate	**Subject**	**Predicate**	**Subject**	**Predicate**	**Subject**
Premise	a	b	a	b	a	c
Premise	b	c	a	c	b	c
Conclusion	a	c	b	c	a	b

Aristotle calls the term which is the predicate of the conclusion the **major** term and the term which is the subject of the conclusion the **minor** term. The premise containing the major term is the **major premise**, and the premise containing the minor term is the **minor premise**.

Aristotle's procedure is then a systematic investigation of the possible combinations of premises in each of the three figures. For each combination, he seeks either to demonstrate that some conclusion necessarily follows or to demonstrate that no conclusion follows. The results he states are exactly correct.

B. Methods of Proof: Conversion and Reduction

Aristotle shows each valid form to be valid by showing how to construct a deduction of its conclusion from its premises. These deductions, in turn, can take one of two forms: **direct** or **probative** (*deiktikos*) deductions and deductions **through the impossible** (*dia to adunaton*).

A direct deduction is a series of steps leading from the premises to the conclusion, each of which is either a **conversion** of a previous step or an inference from two previous steps relying on a first-figure deduction. Conversion, in turn, is inferring from a proposition another which has the subject and predicate interchanged. Specifically, Aristotle argues that three such conversions are sound:

- Eab → Eba
- Iab → Iba
- Aab → Iba

He undertakes to justify these in *An. Pr.* I.2. From a modern standpoint, the third is sometimes regarded with suspicion. Using it we can get *Some monsters are chimeras* from the apparently true *All chimeras are monsters*; but the former is often construed as implying in turn *There is something which is a monster and a chimera*, and thus that there are monsters and there are chimeras. In fact, this simply points up something about Aristotle's system: Aristotle in effect supposes that *all* terms in syllogisms are non-empty. (For further discussion of this point, see the entry on the Square of Opposition).

As an example of the procedure, we may take Aristotle's proof of *Camestres*. He says:

> If M belongs to every N but to no X, then neither will N belong to any X. For if M belongs to no X, then neither does X belong to any M; but M belonged to every N; therefore, N will belong to no M (for the first figure has come about). And since the privative converts, neither will N belong to any X. (*An. Pr.* I.5, 27a9-12)

From this text, we can extract an exact formal proof, as follows:

Step	**Justification**	**Aristotle's Text**
1. MaN		*If M belongs to every N*
2. MeX		*but to no X,*
To prove: NeX		*then neither will N belong to any X.*
3. MeX	(2, premise)	*For if M belongs to no X,*
4. XeM	(3, conversion of *e*)	*then neither does X belong to any M;*
5. MaN	(1, premise)	*but M belonged to every N;*
6. XeN	(4, 5, *Celarent*)	*therefore, X will belong to no N (for the first figure has come about).*
7. NeX	(6, conversion of *e*)	*And since the privative converts, neither will N belong to any X.*

C. Methods of Disproof: Counterexamples and Terms

Aristotle proves invalidity by constructing counterexamples. This is very much in the spirit of modern logical theory: all that it takes to show that a certain *form* is invalid is a single *instance* of that form with true premises and a false conclusion. However, Aristotle states his results not by saying that certain premise-conclusion combinations are invalid but by saying that certain premise pairs do not "syllogize":

that is, that, given the pair in question, examples can be constructed in which premises of that form are true and a conclusion of any of the four possible forms is false.

When possible, he does this by a clever and economical method: he gives two triplets of terms, one of which makes the premises true and a universal affirmative "conclusion" true, and the other of which makes the premises true and a universal negative "conclusion" true. The first is a counterexample for an argument with either an E or an O conclusion, and the second is a counterexample for an argument with either an A or an I conclusion.

D. The Deductions in the Figures ("Moods")

In *Prior Analytics* I.4-6, Aristotle shows that the premise combinations given in the following table yield deductions and that all other premise combinations fail to yield a deduction. in the terminology traditional since the middle ages, each of these combinations is known as a **mood** (from Latin *modus*, "way", which in turn is a translation of Greek *tropos*). Aristotle, however, does not use this expression and instead refers to "the arguments in the figures".

In this table, "⊢" separates premises from conclusion; it may be read "therefore". The second column lists the medieval mnemonic name associated with the inference (these are still widely used, and each is actually a mnemonic for Aristotle's proof of the mood in question). The third column briefly summarizes Aristotle's procedure for demonstrating the deduction.

Table of the Deductions in the Figures

Form	**Mnemonic**	**Proof**
Aab, Abc ⊢ Aac	*Barbara*	Perfect
Eab, Abc ⊢ Eac	*Celarent*	Perfect
Aab, Ibc ⊢ Iac	*Darii*	Perfect; also by impossibility, from *Camestres*
Eab, Ibc ⊢ Oac	*Ferio*	Perfect; also by impossibility, from *Cesare*
SECOND FIGURE		
Eab, Aac ⊢ Ebc	*Cesare*	(Eab, Aac)→(Eba, Aac)$\vdash_{Cel}$Ebc
Aab, Eac ⊢ Ebc	*Camestres*	(Aab, Eac)→(Aab, Eca)=(Eca, Aab)$\vdash_{Cel}$Ecb→Ebc
Eab, Iac ⊢ Obc	*Festino*	(Eab, Iac)→(Eba, Iac)$\vdash_{Fer}$Obc
Aab, Oac ⊢ Obc	*Baroco*	(Aab, Oac +Abc)$\vdash_{Bar}$(Aac, Oac)$\vdash_{Imp}$Obc
THIRD FIGURE		
Aac, Abc ⊢ Iab	*Darapti*	(Aac, Abc)→(Aac, Icb)$\vdash_{Dar}$Iab

Eac, Abc ⊢ Oab	*Felapton*	(Eac, Abc)→(Eac, Icb)$\vdash_{Fer}$Oab
Iac, Abc ⊢ Iab	*Disamis*	(Iac, Abc)→(Ica, Abc)=(Abc, Ica)$\vdash_{Dar}$Iba→Iab
Aac, Ibc ⊢ Iab	*Datisi*	(Aac, Ibc)→(Aac, Icb)$\vdash_{Dar}$Iab
Oac, Abc ⊢ Oab	*Bocardo*	(Oac, +Aab, Abc)$\vdash_{Bar}$(Aac, Oac)$\vdash_{Imp}$Oab
Eac, Ibc ⊢ Oab	*Ferison*	(Eac, Ibc)→(Eac, Icb)$\vdash_{Fer}$Oab

E. Metatheoretical Results

Having established which deductions in the figures are possible, Aristotle draws a number of metatheoretical conclusions, including:

1. No deduction has two negative premises
2. No deduction has two particular premises
3. A deduction with an affirmative conclusion must have two affirmative premises
4. A deduction with a negative conclusion must have one negative premise.
5. A deduction with a universal conclusion must have two universal premises

He also proves the following metatheorem:

> All deductions can be reduced to the two universal deductions in the first figure.

His proof of this is elegant. First, he shows that the two particular deductions of the first figure can be reduced, by proof through impossibility, to the universal deductions in the second figure:

> (*Darii*)(Aab, Ibc, +Eac)$\vdash_{Camestres}$(Ebc, Ibc)$\vdash_{Imp}$Iac
> (*Feri*)(Eab, Ibc, +Aac)$\vdash_{Cesare}$(Ebc, Ibc)$\vdash_{Imp}$Oac

He then observes that since he has already shown how to reduce all the particular deductions in the other figures except Baroco and Bocardo to *Darii* and *Ferio*, these deductions can thus be reduced to *Barbara* and *Celarent*. This proof is strikingly similar both in structure and in subject to modern proofs of the redundancy of axioms in a system.

Many more metatheoretical results, some of them quite sophisticated, are proved in *Prior Analytics* I.45 and in *Prior Analytics* II. As noted below, some of Aristotle's metatheoretical results are appealed to in the epistemological arguments of the *Posterior Analytics*.

F. Syllogisms with Modalities

Aristotle follows his treatment of "arguments in the figures" with a much longer, and much more problematic, discussion of what happens to these figured arguments when we add the qualifications "necessarily" and "possibly" to their premises in various ways. In contrast to the syllogistic itself (or, as commentators like to call it, the *assertoric* syllogistic), this *modal* syllogistic appears to be much less satisfactory and is certainly far more difficult to interpret. Here, I only outline Aristotle's treatment of this subject and note some of the principal points of interpretive controversy.

The Definitions of the Modalities

Modern modal logic treats necessity and possibility as interdefinable: "necessarily P" is equivalent to "not possibly not P", and "possibly P" to "not necessarily not P". Aristotle gives these same equivalences in *On Interpretation*. However, in *Prior Analytics*, he makes a distinction between two notions of possibility. On the first, which he takes as his preferred notion, "possibly P" is equivalent to "not necessarily P and not necessarily not P". He then acknowledges an alternative definition of possibility according to the modern equivalence, but this plays only a secondary role in his system.

Aristotle's General Approach

Aristotle builds his treatment of modal syllogisms on his account of non-modal (**assertoric**) syllogisms: he works his way through the syllogisms he has already proved and considers the consequences of adding a modal qualification to one or both premises. Most often, then, the questions he explores have the form: "Here is an assertoric syllogism; if I add these modal qualifications to the premises, then what modally qualified form of the conclusion (if any) follows?". A premise can have one of three modalities: it can be necessary, possible, or assertoric. Aristotle works through the combinations of these in order:

- Two necessary premises
- One necessary and one assertoric premise
- Two possible premises
- One assertoric and one possible premise
- One necessary and one possible premise

Though he generally considers only premise combinations which syllogize in their assertoric forms, he does sometimes extend this; similarly, he sometimes considers conclusions in addition to those which would follow from purely assertoric premises.

Since this is his procedure, it is convenient to describe modal syllogisms in terms of the corresponding non-modal syllogism plus a triplet of letters indicating the modalities of premises and conclusion: N = "necessary", P = "possible", A = "assertoric". Thus, "Barbara NAN" would mean "The form *Barbara* with necessary major premise, assertoric minor premise, and necessary conclusion". I use the letters "N" and "P" as prefixes for premises as well; a premise with no prefix is assertoric. Thus, *Barbara* NAN would be NAab, Abc, ⊢ NAac.

Modal Conversions

As in the case of assertoric syllogisms, Aristotle makes use of conversion rules to prove validity. The conversion rules for necessary premises are exactly analogous to those for assertoric premises:

- NEab→NEba
- NIab→NIba
- NAab→NIba

Possible premises behave differently, however. Since he defines "possible" as "neither necessary nor impossible", it turns out that *x is possibly F* entails, and is entailed by, *x is possibly not F*. Aristotle generalizes this to the case of categorical sentences as follows:

- PAab→PEab
- PEab→PAab
- PIab→POab
- POab→PIab

In addition, Aristotle uses the intermodal principle N→A: that is, a necessary premise entails the corresponding assertoric one. However, because of his definition of possibility, the principle A→P does not generally hold: if it did, then N→P would hold, but on his definition "necessarily P" and "possibly P" are actually inconsistent ("possibly P" entails "possibly not P").

This leads to a further complication. The denial of "possibly P" for Aristotle is "either necessarily P or necessarily not P". The denial of "necessarily P" is still more difficult to express in terms of a combination of modalities: "either possibly P (and thus possibly not P) or necessarily not P" This is important because of Aristotle's proof procedures, which include proof through impossibility. If we give a proof through impossibility in which we assume a necessary premise, then the conclusion we ultimately establish is simply the denial of that necessary premise, not a "possible" conclusion in Aristotle's sense. Such propositions do occur in his system, but only in exactly this way, i.e. as conclusions established by proof through impossiblity from necessary assumptions. Somewhat confusingly, Aristotle calls such propositions "possible" but immediately adds " not in the sense defined": in this sense, "possibly Oab" is simply the denial of "necessarily Aab". Such propositions appear only as premises, never as conclusions.

Syllogisms with Necessary Premises

Aristotle holds that an assertoric syllogism remains valid if "necessarily" is added to its premises and its conclusion: the modal pattern NNN is always valid. He does not treat this as a trivial consequence but instead offers proofs; in all but two cases, these are parallel to those offered for the assertoric case. The exceptions are *Baroco* and *Bocardo*, which he proved in the assertoric case through impossibility: attempting to use that method here would require him to take the denial of a necessary O proposition as hypothesis, raising the complication noted above, and he must resort to a different form of proof instead.

NA/AN Combinations: The Problem of the "Two Barbaras" and Other Difficulties

Since a necessary premise entails an assertoric premise, every AN or NA combination of premises will entail the corresponding AA pair, and thus the corresponding A conclusion. Thus, ANA and NAA syllogisms are always valid. However, Aristotle holds that some, but not all, ANN and NAN combinations are valid. Specifically, he accepts *Barbara* NAN but rejects *Barbara* ANN. Almost from Aristotle's own time, interpreters have found his reasons for this distinction obscure, or unpersuasive, or both. Theophrastus, for instance, adopted the simpler rule that the modality of the conclusion of a syllogism was always the "weakest" modality found in either premise, where N is stronger than A and A is stronger than P (and where P probably has to be defined as "not necessarily not"). Other difficulties follow from the problem of the "Two Barbaras", as it is often called, and it has often been maintained that the modal syllogistic is inconsistent.

This subject quickly becomes too complex for summarizing in this brief article. For further discussion, see Becker, McCall, Patterson, van Rijen, Striker, Nortmann, Thom, and Thomason.

§6: Demonstrations and Demonstrative Sciences

A **demonstration** (*apodeixis*) is "a deduction that produces knowledge". Aristotle's *Posterior Analytics* contains his account of demonstrations and their role in knowledge. From a modern perspective, we might think that this subject moves outside of logic to epistemology. From Aristotle's perspective, however, the connection of the theory of *sullogismoi* with the theory of knowledge is especially close.

A. Aristotelian Sciences

The subject of the *Posterior Analytics* is *epistêmê*. This is one of several Greek words that can reasonably be translated "knowledge", but Aristotle is concerned only with knowledge of a certain type (as will be explained below). There is a long tradition of translating *epistêmê* in this technical sense as **science**, and I shall follow that tradition here. However, readers should not be misled by the use of that word. In particular, Aristotle's theory of science cannot be considered a counterpart to modern philosophy of science, at least not without substantial qualifications.

We have scientific knowledge, according to Aristotle, when we know:

> the cause why the thing is, that it is the cause of this, and that this cannot be otherwise. (*Posterior Analytics* I.2)

This implies two strong conditions on what can be the object of scientific knowledge:

1. Only what is necessarily the case can be known scientifically

2. Scientific knowledge is knowledge of causes

He then proceeds to consider what science so defined will consist in, beginning with the observation that at any rate one form of science consists in the possession of a **demonstration** (*apodeixis*), which he defines as a "scientific deduction":

> by "scientific" (*epistêmonikon*), I mean that in virtue of possessing it, we have knowledge.

The remainder of *Posterior Analytics* I is largely concerned with two tasks: spelling out the nature of demonstration and demonstrative science and answering an important challenge to its very possibility. Aristotle first tells us that a demonstration is a deduction in which the premises are:

1. true
2. **primary** (*prota*)
3. **immediate** (*amesa*, "without a middle")
4. **better known** or **more familiar** (*gnôrimôtera*) than the conclusion
5. **prior** to the conclusion
6. **causes** (*aitia*) of the conclusion

The interpretation of all these conditions except the first has been the subject of much controversy. Aristotle clearly thinks that science is knowledge of causes and that in a demonstration, knowledge of the premises is what brings about knowledge of the conclusion. The fourth condition shows that the knower of a demonstration must be in some better epistemic condition towards them, and so modern interpreters often suppose that Aristotle has defined a kind of epistemic justification here. However, as noted above, Aristotle is defining a special variety of knowledge. Comparisons with discussions of justification in modern epistemology may therefore be misleading.

The same can be said of the terms "primary", "immediate" and "better known". Modern interpreters sometimes take "immediate" to mean "self-evident"; Aristotle does say that an immediate proposition is one "to which no other is prior", but (as I suggest in the next section) the notion of priority involved is likely a notion of logical priority that it is hard to detach from Aristotle's own logical theories. "Better known" has sometimes been interpreted simply as "previously known to the knower of the demonstration" (i.e. already known in advance of the demonstration). However, Aristotle explicitly distinguishes between what is "better known for us" with what is "better known in itself" or "in nature" and says that he means the latter in his definition. In fact, he says that the process of acquiring scientific knowledge is a process of *changing* what is better known "for us", until we arrive at that condition in which what is better known in itself is also better known for us.

B. The Regress Problem

In *Posterior Analytics* I.2, Aristotle considers two challenges to the possibility of science. One party (dubbed the "agnostics" by Jonathan Barnes) began with the following two premises:

1. Whatever is scientifically known must be demonstrated.
2. The premises of a demonstration must be scientifically known.

They then argued that demonstration is impossible with the following dilemma:

1. If the premises of a demonstration are scientifically known, then they must be demonstrated.
2. The premises from which each premise are demonstrated must be scientifically known.
3. Either this process continues forever, creating an infinite regress of premises, or it comes to a stop at some point.
4. If it continues forever, then there are no first premises from which the subsequent ones are demonstrated, and so nothing is demonstrated.
5. On the other hand, if it comes to a stop at some point, then the premises at which it comes to a stop are undemonstrated and therefore not scientifically known; consequently, neither are any of the others deduced from them.
6. Therefore, nothing can be demonstrated.

A second group accepted the agnostics' view that scientific knowledge comes only from demonstration but rejected their conclusion by rejecting the dilemma. Instead, they maintained:

- Demonstration "in a circle" is possible, so that it is possible for all premises also to be conclusions and therefore demonstrated.

Aristotle does not give us much information about how circular demonstration was supposed to work, but the most plausible interpretation would be supposing that at least for some set of fundamental principles, each principle could be deduced from the others. (Some modern interpreters have compared this position to a coherence theory of knowledge.) However their position worked, the circular demonstrators claimed to have a third alternative avoiding the agnostics' dilemma, since circular demonstration gives us a regress that is both unending (in the sense that we never reach premises at which it comes to a stop) and finite (because it works its way round the finite circle of premises).

C. Aristotle's Solution: "It Eventually Comes to a Stop"

Aristotle rejects circular demonstration as an incoherent notion on the grounds that the premises of any demonstration must be prior (in an appropriate sense) to the conclusion, whereas a circular demosntration would make the same premises both prior and posterior to one another (and indeed every premise prior and posterior to itself). He agrees with the agnostics' analysis of the regress problem: the only plausible options are that it continues indefinitely or that it "comes to a stop" at some point. However, he thinks both the agnostics and the circular demosntrators are wrong in maintaining that scientific knowledge is only possible by demonstration from premises scientifically known: instead, he claims, there is another form of knowledge possible for the first premises, and this provides the starting points for demonstrations.

To solve this problem, Aristotle needs to do something quite specific. It will not be enough for him to establish that we can have knowledge of *some propositions* without demonstrating them: unless it is in turn possible to deduce all the other propositions of a science from them, we shall not have solved the regress problem. Moreover (and obviously), it is no solution to this problem for Aristotle simply to *assert* that we have knowledge without demonstration of some appropriate starting points. He does indeed say that it is his position that we have such knowledge (*An. Post.* I.2,), but he owes us an account of why that should be so.

D. Knowledge of First Principles: *Nous*

Aristotle's account of knowledge of the indemonstrable first premises of sciences is found in *Posterior Analytics* II.19, long regarded as a difficult text to interpret. Briefly, what he says there is that it is another cognitive state, *nous* (translated variously as "insight", "intuition", "intelligence"), which knows them. There is wide disagreement among commentators about the interpretation of his account of how this state is reached; I will offer one possible interpretation. First, Aristotle identifies his problem as explaining how the principles can "become familiar to us", using the same term "familiar" (*gnôrimos*) that he used in presenting the regress problem. What he is presenting, then, is not a method of discovery but a process of becoming wise. Second, he says that in order for knowledge of immediate premises to be possible, we must have a kind of knowledge of them without having learned it, but this knowledge must not be as "precise" as the knowledge that a possessor of science must have. The kind of knowledge in question turns out to be a capacity or power (*dunamis*) which Aristotle compares to the the capacity for sense-perception: since our senses are innate, i.e. develop naturally, it is in a way correct to say that we know what e.g. all the colors look like before we have seen them: we have the capacity to see them by nature, and when we first see a color we exercise this capacity without having to learn how to do so first. Likewise, Aristotle holds, our minds have by nature the capacity to recognize the starting points of the sciences.

In the case of sensation, the capacity for perception in the sense organ is actualized by the operation on it of the perceptible object. Similarly, Aristotle holds that coming to know first premises is a matter of a potentiality in the mind being actualized by experience of its proper objects: "The soul is of such a nature as to be capable of undergoing this". So, although we cannot come to know the first premises without the necessary experience, just as we cannot see colors without the presence of colored objects, our minds are already so constituted as to be able to recognize the right objects, just as our eyes are already so constituted as to be able to perceive the colors that exist.

It is considerably less clear what these objects are and how it is that experience actualizes the relevant potentialities in the soul. Aristotle describes a series of stages of cognition. First is what is common to all animals: perception of what is present. Next is memory, which he regards as a retention of a sensation: only some animals have this capacity. Even fewer have the next capacity, the capacity to form a single experience (*empeiria*) from many repetitions of the same memory. Finally, many experiences repeated give rise to knowledge of a single universal (*katholou*). This last capacity is present only in humans.

See the article on Aristotle's psychology for more on his views about mind.

§7: Definitions

The **definition** (*horos*, *horismos*) was an important matter for Plato and for the Early Academy. Concern with answering the question "What is so-and-so?" are at the center of the majority of Plato's dialogues, some of which (most elaborately the *Sophist*) propound methods for finding definitions. External sources (sometimes the satirical remarks of comedians) also reflect this Academic concern with definitions. Aristotle himself traces the quest for definitions back to Socrates.

A. Definitions and Essences

For Aristotle, a definition is "an account which signifies what it is to be for something" (*logos ho to ti ên einai sêmainei*). The phrase "what it is to be" and its variants are crucial: giving a definition is saying, of some existent thing, what it is, not simply specifying the meaning of a word (Aristotle does recognize definitions of the latter sort, but he has little interest in them).

The notion of "what it is to be" for a thing is so pervasive in Aristotle that it becomes formulaic: what a definition expresses is "the what-it-is-to-be" (*to ti ên einai*). Roman translators, vexed by this odd Greek phrase, devised a word for it, *essentia*, from which our "essence" descends. So, an Aristotelian definition is an account of the essence of something.

B. Species, Genus, and Differentia

Since a definition defines an essence, only what has an essence can be defined. What has an essence, then? That is one of the central questions of Aristotle's metaphysics; once again, we must leave the details to another article. In general, however, it is not individuals but rather **species** (*eidos*: the word is one of those Plato uses for "Form") that have essences. A species is defined by giving its **genus** (*genos*) and its **differentia** (*diaphora*): the genus is the kind under which the species falls, and the differentia tells what characterizes the species within that genus. As an example, *human* might be defined as *animal* (the genus) *having the capacity to reason* (the differentia).

Essential Predication and the Predicables

Underlying Aristotle's concept of a definition is the concept of **essential predication** (*katêgoreisthai en tôi ti esti*, predication in the what it is). In any true affirmative predication, the predicate either does or does not "say what the subject is", i.e., the predicate either is or is not an acceptable answer to the question "What is it?" asked of the subject. Bucephalus is a horse, and a horse is an animal; so, "Bucephalus is a horse" and "Bucephalus is an animal" are essential predications. However, "Bucephalus is brown", though true, does not state what Bucephalus us but only says something about him.

Since a thing's definition says what it is, definitions are essentially predicated. However, not everything essentially predicated is a definition. Since Bucephalus is a horse, and horses are a kind of mammal, and mammals are a kind of animal, "horse" "mammal" and "animal" are all essential predicates of Bucephalus. Moreover, since what a horse is is a kind of mammal, "mammal" is an essential predicate of horse. When predicate X is an essential predicate of Y but also of other things, then X is a **genus** (*genos*) of Y.

A definition of X must not only be essentially predicated of it but must also be predicated only of it: to use a term from Aristotle's *Topics*, a definition and what it defines must "counterpredicate" (*antikatêgoreisthai*) with one another. X counterpredicates with Y if X applies to what Y applies to and conversely. Though X's definition must counterpredicate with X, not everything that counterpredicates with X is its definition. "Capable of laughing", for example, counterpredicates with "human" but fails to be its definition. Such a predicate (non-essential but counterpredicating) is a **peculiar property** or **proprium** (*idion*).

Finally, if X is predicated of Y but is neither essential nor counterpredicates, then X is an **accident** (*sumbebêkos*) of Y.

Aristotle sometimes treats genus, peculiar property, definition, and accident as including all possible predications (e.g. *Topics* I). Later commentators listed these four and the differentia as the five **predicables**, and as such they were of great importance to late ancient and to medieval philosophy (e.g., Porphyry).

C. The Categories

The notion of essential predication is connected to what are traditionally called the **categories** (*katêgoriai*). In a word, Aristotle is famous for having held a "doctrine of categories". Just what that doctrine was, and indeed just what a category is, are considerably more vexing questions. They also quickly take us outside his logic and into his metaphysics. Here, I will try to give a very general overview, beginning with the somewhat simpler question "What categories are there?"

We can answer this question by listing the categories. Here are two passages containing such lists:

> We should distinguish the kinds of predication (*ta genê tôn katêgoriôn*) in which the four predications mentioned are found. These are ten in number: what-it-is, quantity, quality, relative, where, when, being-in-a-position, having, doing, undergoing. An accident, a genus, a peculiar property and a definition will always be in one of these categories. (*Topics* I.9, 103b20-25)

> Of things said without any combination, each signifies either substance or quantity or quality or a relative or where or when or being-in-a-position or having or doing or undergoing. To give a rough idea, examples of substance are man, horse; of quantity: four-

> foot, five-foot; of quality: white, literate; of a relative: double, half, larger; of where: in the Lyceum, in the market-place; of when: yesterday, last year; of being-in-a-position: is-lying, is-sitting; of having: has-shoes-on, has-armor-on; of doing: cutting, burning; of undergoing: being-cut, being-burned. (*Categories* 4, 1b25-2a4, tr. Ackrill, slightly modified)

These two passages give ten-item lists, identical except for their first members. What are they lists *of*? Here are three ways they might be interpreted:

The word "category" (*katêgoria*) means "predication". Aristotle holds that predications and predicates can be grouped into several largest "kinds of predication" (*genê tôn katêgoriôn*). He refers to this classification frequently, often calling the "kinds of predication" simply "the predications", and this (by way of Latin) leads to our word "category".

- First, the categories may be *kinds of predicate*: predicates (or, more precisely, predicate expressions) can be divided into ten separate classes, with each expression belonging to just one class. This comports well with the root meaning of the word *katêgoria* ("predication"). On this interpretation, the categories arise out of considering the most general types of question that can be asked about something: "*What* is it?"; "*How much* is it?"; "*What sort* is it?"; "*Where* is it?"; "*What* is it *doing*?" Answers appropriate to one of these questions are nonsensical in response to another ("When is it?" "A horse"). Thus, the categories may rule out certain kinds of question as ill-formed or confused. This plays an important role in Aristotle's metaphysics.
- Second, the categories may be seen as classifications of *predications*, that is, kinds of relation that may hold between the predicate and the subject of a predication. To say of Socrates that he is human is to say what he *is*, whereas to say that he is literate is not to say what he is but rather to give a quality that he *has*. For Aristotle, the relation of predicate to subject in these two sentences is quite different (in this respect he differs both from Plato and from modern logicians). The categories may be interpreted as ten different ways in which a predicate may be related to its subject. This last division has importance for Aristotle's logic as well as his metaphysics.
- Third, the categories may be seen as *kinds of entity*, as highest genera or kinds of thing that are. A given thing can be classified under a series of progressively wider genera: Socrates is a human, a mammal, an animal, a living being. The categories are the highest such genera. Each falls under no other genus, and each is completely separate from the others. This distinction is of critical importance to Aristotle's metaphysics.

Which of these interpretations fits best with the two passages above? The answer appears to be different in the two cases. This is most evident if we take note of point in which they differ: the *Categories* lists **substance** (*ousia*) in first place, while the *Topics* list **what-it-is** (*ti esti*). A substance, for Aristotle, is a type of entity, suggesting that the *Categories* list is a list of types of entity.

On the other hand, the expression "what-it-is" suggests most strongly a type of predication. Indeed, the *Topics* confirms this by telling us that we can "say what it is" of an *entity* falling under any of the categories:

> an expression signifying what-it-is will sometimes signify a substance, sometimes a quantity, sometimes a quality, and sometimes one of the other categories.

As Aristotle explains, if I say that Socrates is a man, then I have said what Socrates is and signified a substance; if I say that white is a color, then I have said what white is and signified a quality; if I say that some length is a foot long, then I have said what it is and signified a quantity; and so on for the other categories. What-it-is, then, here designates a kind of predication, not a kind of entity.

This might lead us to conclude that the categories in the *Topics* are only to be interpreted as kinds of predicate or predication, those in the *Categories* as kinds of being. Even so, we would still want to ask what the relationship is between these two nearly-identical lists of terms, given these distinct interpretations. However, the situation is much more complicated. First, there are dozens of other passages in which the categories appear. Nowhere else do we find a list of ten, but we do find shorter lists containing eight, or six, or five, or four of them (with substance/what-it-is, quality, quantity, and relative the most common). Aristotle describes what these lists are lists of in different ways: they tell us "how being is divided", or "how many ways being is said", or "the figures of predication" (ta schêmata tês katêgorias). The designation of the first category also varies: we find not only "substance" and "what it is" but also the expressions "this" or "the this" (*tode ti, to tode, to ti*). These latter expressions are closely associated with, but not synonymous with, substance. He even combines the latter with "what-it-is" (*Metaphysics* Z 1, 1028a10: ". . . one sense signifies what it is and the this, one signifies quality . . .").

Moreover, substances are for Aristotle fundamental for predication as well as metaphysically fundamental. He tells us that everything that exists exists because substances exist: if there were no substances, there would not be anything else. He also conceives of predication as reflecting a metaphysical relationship (or perhaps more than one, depending on the type of predication). The sentence "Socrates is pale" gets its truth from a state of affairs consisting of a substance (Socrates) and a quality (whiteness) which is in that substance. At this point we have gone far outside the realm of Aristotle's logic into his metaphysics, the fundamental question of which, according to Aristotle, is "What is a substance?". (For further discussion of this topic, see the entry on Aristotle's metaphysics, and in particular, Section 2 on the categories.)

See Frede 1981, Ebert 1985 for additional discussion of Aristotle's lists of categories.

For convenience of reference, I include a table of the categories, along with Aristotle's examples and the traditional names often used for them. For reasons explained above, I have treated the first item in the list quite differently, since an example of a substance and an example of a what-it-is are necessarily (as one might put it) in different categories.

Traditional name	Literally	Greek	Examples

(Substance)	substance "this" what-it-is	*ousia* *tode ti* *ti esti*	man, horse Socrates "Socrates is a man"
Quantity	How much	*poson*	four-foot, five-foot
Quality	What sort	*poion*	white, literate
Relation	related to what	*pros ti*	double, half, greater
Location	Where	*pou*	in the Lyceum, in the marketplace
Time	when	*pote*	yesterday, last year
Position	being situated	*keisthai*	lies, sits
Habit	having, possession	*echein*	is shod, is armed
Action	doing	*poiein*	cuts, burns
Passion	undergoing	*paschein*	is cut, is burned

D. The Method of Division

In the *Sophist*, Plato introduces a procedure of "Division" as a method for discovering definitions. To find a definition of X, first locate the largest kind of thing under which X falls; then, divide that kind into two parts, and decide which of the two X falls into. Repeat this method with the part until X has been fully located.

This method is part of Aristotle's Platonic legacy. His attitude towards it, however, is complex. He adopts a view of the proper structure of definitions that is closely allied to it: a correct definition of X should give the **genus** (*genos*: kind or family) of X, which tells what kind of thing X is, and the **differentia** (*diaphora*: difference) which uniquely identifies X within that genus. Something defined in this way is a **species** (*eidos*: the term is one of Plato's terms for "Form"), and the differentia is thus the "difference that makes a species" (*eidopoios diaphora*, "specific difference"). In *Posterior Analytics* II.13, he gives his own account of the use of Division in finding definitions.

However, Aristotle is strongly critical of the Platonic view of Division as a method for *establishing* definitions. In *Prior Analytics* I.31, he contrasts Division with the syllogistic method he has just presented, arguing that Division cannot actually prove anything but rather assumes the very thing it is supposed to be proving. He also charges that the partisans of Division failed to understand what their own method was capable of proving.

E. Definition and Demonstration

Closely related to this is the discussion, in *Posterior Analytics* II.3-10, of the question whether there can be both definition and demonstration of the same thing. Since the definitions Aristotle is interested in are

statements of essences, knowing a definition is knowing, of some existing thing, what it is. Consequently, Aristotle's question amounts to a question whether defining and demonstrating can be alternative ways of acquiring the same knowledge. His reply is complex:

1. Not everything demonstrable can be known by finding definitions, since all definitions are universal and affirmative whereas some demonstrable propositions are negative.
2. If a thing is demonstrable, then to know it just is to possess its demonstration; therefore, it cannot be known just by definition.
3. Nevertheless, some definitions can be understood as demonstrations differently arranged.

As an example of case 3, Aristotle considers the definition "Thunder is the extinction of fire in the clouds". He sees this as a compressed and rearranged form of this demonstration:

- Sound accompanies the extinguishing of fire.
- Fire is extinguished in the clouds.
- Therefore, a sound occurs in the clouds.

We can see the connection by considering the answers to two questions: "What is thunder?" "The extinction of fire in the clouds" (definition). "Why does it thunder?" "Because fire is extinguished in the clouds" (demonstration).

As with his criticisms of Division, Aristotle is arguing for the superiority of his own concept of science to the Platonic concept. Knowledge is composed of demonstrations, even if it may also include definitions; the method of science is demonstrative, even if it may also include the process of defining.

§8: Dialectical Argument and the Art of Dialectic

Aristotle often contrasts *dialectical arguments* with demonstrations. The difference, he tells us, is in the character of their premises, not in their logical structure: whether an argument is a *sullogismos* is only a matter of whether its conclusion results of necessity from its premises. The premises of demonstrations must be *true and primary*, that is, not only true but also prior to their conclusions in the way explained in the *Posterior Analytics*. The premises of dialectical deductions, by contrast, must be **accepted** (*endoxos*).

A. Dialectical Premises: The Meaning of *Endoxos*

Recent scholars have proposed different interpretations of the term *endoxos*. Aristotle often uses this adjective as a substantive: *ta endoxa*, "accepted things", "accepted opinions". On one understanding, descended from the work of G. E. L. Owen and developed more fully by Jonathan Barnes and especially Terence Irwin, the *endoxa* are a compilation of views held by various people with some form or other of standing: "the views of fairly reflective people after some reflection", in Irwin's phrase. Dialectic is then simply "a method of argument from [the] common beliefs [held by these people]". For Irwin, then,

endoxa are "common beliefs". Jonathan Barnes, noting that *endoxa* are opinions with a certain standing, translates with "reputable".

My own view is that Aristotle's texts support a somewhat different understanding. He also tells us that dialectical premises differ from demonstrative ones in that the former are *questions*, whereas the latter are *assumptions* or *assertions*: "the demonstrator does not ask, but takes", he says. This fits most naturally with a view of dialectic as argument directed at another person by question and answer and consequently taking as premises that other person's concessions. Anyone arguing in this manner will, in order to be successful, have to ask for premises which the interlocutor is liable to accept, and the best way to be successful at that is to have an inventory of acceptable premises, i.e. premises that are in fact acceptable to people of different types.

In fact, we can discern in the *Topics* (and the *Rhetoric*, which Aristotle says depends on the art explained in the *Topics*) an art of dialectic for use in such arguments. My reconstruction of this art (which would not be accepted by all scholars) is as follows.

B. The Two Elements of the Art of Dialectic

Given the above picture of dialectical argument, the dialectical art will consist of two elements. One will be a method for discovering premises from which a given conclusion follows, while the other will be a method for determining which premises a given interlocutor will be likely to concede. The first task is accomplished by developing a system for classifying premises according to their logical structure. We might expect Aristotle to avail himself here of the syllogistic, but in fact he develops quite another approach, one that seems less systematic and rests on various "common" terms. The second task is accomplished by developing lists of the premises which are acceptable to various types of interlocutor. Then, once one knows what sort of person one is dealing with, one can choose premises accordingly. Aristotle stresses that, as in all arts, the dialectician must study, not what is acceptable to this or that specific person, but what is acceptable to this or that type of person, just as the doctor studies what is healthful for different types of person: "art is of the universal".

The "Logical System" of the *Topics*

The method presented in the *Topics* for classifying arguments relies on the presence in the conclusion of certain "common" terms (*koina*) -- common in the sense that they are not peculiar to any subject matter but may play a role in arguments about anything whatever. We find enumerations of arguments involving these terms in a similar order several times. Typically, they include:

I. Opposites (*antikeimena*, *antitheseis*)
    1. Contraries (*enantia*)
    2. Contradictories (*apophaseis*)
    3. Possession and Privation (*hexis kai sterêsis*)
    4. Relatives (*pros ti*)

II. Cases (*ptôseis*)
III. "More and Less and Likewise"

The four types of **opposites** are the best represented. Each designates a type of term pair, i.e. a way two terms can be opposed to one another. **Contraries** are polar opposites or opposed extremes such as hot and cold, dry and wet, good and bad. A pair of **contradictories** consists of a term and its negation: good, not good. A **possession** (or condition) and **privation** are illustrated by sight and blindness.**Relatives** are relative terms in the modern sense: a pair consists of a term and its correlative, e.g. large and small, parent and child.

The argumentative patterns Aristotle associated with **cases** generally involve inferring a sentence contaning adverbial or declined forms from another sentence containing different forms of the same word stem: "if what is useful is good, then what is done usefully is done well and the useful person is good". In Hellenistic grammatical usage, *ptôsis* meant "case" (e.g. nominative, dative, accusative); Aristotle's use here is obviously an early form of that.

Under the heading **more and less and likewise**, Aristotle groups a somewhat motley assortment of argument patterns all involving, in some way or other, the terms "more", "less", and "likewise". Examples: "If whatever is A is B, then whatever is more (less) A is more (less) B"; "If A is more likely B than C is, and A is not B, then neither is C"; "If A is more likely than B and B is the case, then A is the case".

The *Topoi*

At the heart of the *Topics* is a collection of what Aristotle calls *topoi*, "places" or "locations". Unfortunately, though it is clear that he intends most of the *Topics* (Books II-VI) as a collection of these, he never explicitly defines this term. Interpreters have consequently disagreed considerably about just what a *topos* is. A discussion may be found in Brunschwig 1967, Slomkowski 1996, Primavesi 1997, and Smith 1997.

C. The Uses of Dialectic and Dialectical Argument

An *art* of dialectic will be useful wherever dialectical argument is useful. Aristotle mentions three such uses; each merits some comment.

Gymnastic Dialectic

First, there appears to have been a form of stylized argumentative exchange practiced in the Academy in Aristotle's time. The main evidence for this is simply Aristotle's *Topics*, especially Book VIII, which makes frequent reference to rule-governed procedures, apparently taking it for granted that the audience will understand them. In these exchanges, one participant took the role of answerer, the other the role of questioner. The answerer began by asserting some proposition (a *thesis*: "position" or "acceptance"). The

questioner then asked questions of the answerer in an attempt to secure concessions from which a contradiction could be deduced: that is, to **refute** (*elenchein*) the answerer's position. The questioner was limited to questions that could be answered by yes or no; generally, the answerer could only respond with yes or no, though in some cases answeres could object to the form of a question. Answerers might undertake to answer in accordance with the views of a particular type of person or a particular person (e.g. a famous philosopher), or they might answer according to their own beliefs. There appear to have been judges or scorekeepers for the process. Gymnastic dialectical contests were sometimes, as the name suggests, for the sake of exercise in developing argumentative skill, but they may also have been pursued as a part of a process of inquiry.

Dialectic That Puts to the Test

Aristotle also mentions an "art of making trial", or a variety of dialectical argument that "puts to the test" (the Greek word is the adjective *peirastikê*, in the feminine: such expressions often designate arts or skills, e.g. *rhêtorikê*, "the art of rhetoric"). Its function is to examine the claims of those who say they have some knowledge, and it can practiced by someone who does not possess the knowledge in question. The examination is a matter of refutation, based on the principle that whoever knows a subject must have consistent beliefs about it: so, if you can show me that my beliefs about something lead to a contradiction, then you have shown that I do not have knowledge about it.

This is strongly reminiscent of Socrates' style of interrogation, from which it is almost certainly descended. In fact, Aristotle often indicates that dialectical argument is by nature refutative.

Dialectic and Philosophy

Dialectical refutation cannot of itself establish any proposition (except perhaps the proposition that some set of propositions is inconsistent). More to the point, though deducing a contradiction from my beliefs may show that they do not constitute knowledge, failure to deduce a contradiction from them is no proof that they are true. Not surprisingly, then, Aristotle often insists that "dialectic does not prove anything" and that the dialectical art is not some sort of universal knowledge.

In *Topics* I.2, however, Aristotle says that the art of dialectic is useful in connection with "the philosophical sciences". One reason he gives for this follows closely on the refutative function: if we have subjected our opinions (and the opinions of our fellows, and of the wise) to a thorough refutative examination, we will be in a much better position to judge what is most likely true and false. In fact, we find just such a procedure at the start of many of Aristotle's treatises: an enumeration of the opinions current about the subject together with a compilation of "puzzles" raised by these opinions. Aristotle has a special term for this kind of review: a *diaporia*, a "puzzling through".

He adds a second use that is both more difficult to understand and more intriguing. The *Posterior Analytics* argues that if anything can be proved, then not everything that is known is known as a result of proof. What alternative means is there whereby the first principles of sciences are known? Aristotle's own

answer as found in *Posterior Analytics* II.19 is difficult to interpret, and recent philosophers have often found it unsatisfying since (as often construed) it appears to commit Aristotle to a form of apriorism or rationalism both indefensible in itself and not consonant with his own insistence on the indispensability of empirical inquiry in natural science.

Against this background, the following passage in *Topics* I.2 may have special importance:

> It is also useful in connection with the first things concerning each of the sciences. For it is impossible to say anything about the science under consideration on the basis of its own principles, since the principles are first of all, and we must work our way through about these by means of what is generally accepted about each. But this is peculiar, or most proper, to dialectic: for since it is examinative with respect to the principles of all the sciences, it has a way to proceed.

A number of interpreters (beginning with Owen 1961) have built on this passage and others to find dialectic at the heart of Aristotle's philosophical method. Further discussion of this issue would take us far beyond the subject of this article (the fullest development is in Irwin 1988; see also Nussbaum 1986 and, for criticism, Hamlyn 1990, Smith 1997).

§9: Dialectic and Rhetoric

Aristotle says that rhetoric, i.e. the study of persuasive speech, is a "counterpart" (*antistrophos*) of dialectic and that the rhetorical art is a kind of "outgrowth" (*paraphues ti*) of dialectic and the study of character types. The correspondence with dialectical method is straightforward: rhetorical speeches, like dialectical arguments, seek to persuade others to accept certain conclusions on the basis of premises they already accept. Therefore, the same measures useful in dialectical contexts will, mutatis mutandis, be useful here: knowing what premises an audience of a given type is likely to believe, and knowing how to find premises from which the desired conclusion follows.

The *Rhetoric* does fit this general description: Aristotle includes both discussions of types of person or audience (with generalizations about what each type tends to believe) and a summary version (in II.23) of the argument patterns discussed in the *Topics*. For further discussion of his rhetoric see Aristotle's rhetoric.

§10: Sophistical Arguments

Demonstrations and dialectical arguments are both forms of valid argument, for Aristotle. However, he also studies what he calls **contentious** (*eristikos*) or **sophistical** arguments: these he defines as arguments which only apparently establish their conclusions. In fact, Aristotle defines these as apparent (but not genuine) *dialectical sullogismoi*. They may have this appearance in either of two ways:

1. Arguments in which the conclusion only appears to follow of necessity from the premises (apparent, but not genuine, *sullogismoi*).
2. Genuine *sullogismois* the premises of which are merely apparently, but not genuinely, acceptable.

Arguments of the first type in modern terms, appear to be valid but are really invalid. Arguments of the second type are at first more perplexing: given that acceptability is a matter of what people believe, it might seem that whatever appears to be *endoxos* must actually be *endoxos*. However, Aristotle probably has in mind arguments with premises that may at first glance *seem* to be acceptable but which, upon a moment's reflection, we immediately realize we don not actually accept. Consider this example from Aristotle's time:

- Whatever you have not lost, you still have.
- You have not lost horns.
- Therefore, you still have horns

This is transparently bad, but the problem is not that it is invalid: the problem is rather that the first premise, though superficially plausible, is false. In fact, anyone with a little ability to follow an argument will realize that at once upon seeing this very argument.

Aristotle's study of sophistical arguments is contained in *On Sophistical Refutations,* which is actually a sort of appendix to the *Topics*.

To a remarkable extent, contemporary discussions of fallacies reproduce Aristotle's own classifications. See Dorion 1995 for further discussion.

§11: Non-Contradiction and Metaphysics

Two frequent themes of Aristotle's account of science are (1) that the first principles of sciences are not demonstrable and (2) that there is no single universal science including all other sciences as its parts. "All things are not in a single genus", he says, "and even if they were, all beings could not fall under the same principles" (*On Sophistical Refutations* 11). Thus, it is exactly the universal applicability of dialectic that leads him to deny it the status of a science.

In *Metaphysics* IV (Γ), however, Aristotle takes what appears to be a different view. First, he argues that there is, in a way, a science that takes being as its genus (his name for it is "first philosophy"). Second, he argues that the principles of this science will be, in a way, the first principles of all (though he does not claim that the principles of other sciences can be demonstrated from them). Third, he identifies one of its first principles as the "most secure" of all principles: the principle of non-contradiction. As he states it,

> It is impossible for the same thing to belong and not belong simultaneously to the same thing in the same respect (*Met.*)

This is the most secure of all principles, Aristotle tells us, because "it is impossible to be in error about it". Since it is a first principle, it cannot be demonstrated; those who think otherwise are "uneducated in analytics". However, Aristotle then proceeds to give what he calls a "refutative demonstration" (*apodeixai elenktikôs*) of this principle.

Further discussion of this principle and Aristotle's arguments concerning it belong to a treatment of his metaphysics (see Aristotle: Metaphysics). However, it should be noted that: (1) these arguments draw on Aristotle's views about logic to a greater extent than any treatise outside the logical works themselves; (2) in the logical works, the principle of non-contradiction is one of Aristotle's favorite illustrations of the "common principles" (*koinai archai*) that underlie the art of dialectic.

See Aristotle's Metaphysics, Dancy 1975, Code 1986 for further discussion.

§12: Time and Necessity: The Sea-Battle

The passage in Aristotle's logical works which has received perhaps the most intense discussion in recent decades is *On Interpretation* 9, where Aristotle discusses the question whether every proposition about the future must be either true or false. Though something of a side issue in its context, the passage raises a problem of great importance to Aristotle's near contemporaries (and perhaps contemporaries).

A **contradiction** (*antiphasis*) is a pair of propositions one of which asserts what the other denies. A major goal of *On Interpretation* is to discuss the thesis that, of every such contradiction, one member must be true and the other false. In the course of his discussion, Aristotle allows for some exceptions. One case is what he calls **indefinite** propositions such as "A man is walking": nothing prevents both this proposition and "A man is not walking" being simultaneously true. This exception can be explained on relatively simple grounds.

A different exception arises for more complex reasons. Consider these two propositions:

1. There will be a sea-battle tomorrow
2. There will not be a sea-battle tomorrow

It seems that exactly one of these must be true and the other false. But if (1) is *now* true, then there *must* be a sea-battle tomorrow, and there *cannot* fail to be a sea-battle tomorrow. The result, according to this puzzle, is that nothing is possible except what actually happens: there are no unactualized possibilities.

Such a conclusion is, as Aristotle is quick to note, a problem both for his own metaphysical views about potentialities and for the commonsense notion that some things are up to us. He therefore proposes another exception to the general thesis concerning contradictory pairs.

This much would probably be accepted by most interpreters. What the restriction is, however, and just what motivates it are matters of wide disagreement. It has been proposed, for instance, that Aristotle adopted, or at least flirted with, a three-valued logic for future propositions, or that he countenanced truth-value gaps, or that his solution includes still more abstruse reasoning. The literature is much too complex to summarize: see Anscombe, Hintikka, D. Frede, Whitaker, Waterlow.

Historically, at least, it is likely that Aristotle is responding to an argument originating in the Megarian School. He ascribes the view that only that which happens is possible to the Megarians in *Metaphysics* IX (Θ). The puzzle with which he is concerned strongly recalls the "Master Argument" of Diodorus Cronus, especially in certain further details. For instance, Aristotle imagines the statement about tomorrow's sea battle having been uttered ten thousand years ago. If it was true, then its truth was a fact about the past; if the past is now unchangeable, then so is the truth value of that past utterance. This recalls the Master Argument's premise that "what is past is necessary". Diodorus Cronus was active a little after Aristotle, and he was a Megarian (see Dorion 1995 for criticism of David Sedley's attempt to reject this). It seems to me reasonable to conclude that Aristotle's target here is some Megarian argument, perhaps an earlier version of the Master.

§13: Glossary of Aristotelian Terminology

- Accept: *tithenai* (in a dialectical argument)
- Accepted: *endoxos* (also 'reputable' 'common belief')
- Accident: *sumbebêkos* (see *incidental*)
- Accidental: *kata sumbebêkos*
- Affirmation: *kataphasis*
- Affirmative: *kataphatikos*
- Assertion: *apophansis* (sentence with a truth value, declarative sentence)
- Assumption: *hupothesis*
- Belong: *huparchein*
- Category: *katêgoria* See the discussion in §C.
- Contradict: *antiphanai*
- Contradiction: *antiphasis* (in the sense "contradictory pair of propositions" and also in the sense "denial of a proposition")
- Contrary: *enantion*
- Deduction: *sullogismos*
- Definition: *horos*, *horismos*
- Demonstration: *apodeixis*
- Denial (of a proposition): *apophasis*
- Dialectic: *dialektikê* (the *art* of dialectic)
- Differentia: *diaphora*; specific difference, *eidopoios diaphora*.
- Direct: *deiktikos* (of proofs; opposed to "through the impossible")
- Essence: *to ti esti*, *to ti ên einai*
- Essential: *en tôi ti esti* (of predications)

- Extreme: *akron* (of the major and minor terms of a deduction)
- Figure: *schêma*
- Form: *eidos* (see also Species)
- Genus: *genos*
- Immediate: *amesos* ("without a middle")
- Impossible: *adunaton*; "through the impossible" (*dia tou adunatou*), of some proofs.
- Incidental: see Accidental
- Induction: *epagôgê*
- Middle, middle term (of a deduction): *meson*
- Negation (of a term): *apophasis*
- Objection: *enstasis*
- Particular: *en merei*, *epi meros* (of a proposition); *kath'hekaston* (of individuals)
- Peculiar, Peculiar Property: *idios, idion*
- Possible: *dunaton, endechomenon*; *endechesthai*(verb: "be possible")
- Predicate: *katêgorein* (verb); *katêegoroumenon*("what is predicated")
- Predication: *katêgoria* (act or instance of predicating, type of predication)
- Primary: *prôton*
- Principle: *archê* (starting point of a demonstration)
- Quality: *poion*
- Reduce, Reduction: *anagein, anagôgê*
- Refute: *elenchein*; refutation, *elenchos*
- Science: *epistêmê*
- Species: *eidos*
- Specific: *eidopoios* (of a differentia that "makes a species",*eidopoios diaphora*)
- Subject: *hupokeimenon*
- Substance: *ousia*
- Term: *horos*
- Universal: *katholou* (both of propositions and of individuals)

Aristotle's Logic: Detailed Table of Contents

Return to Section 1: Introduction

The Traditional Square of Opposition

This entry traces the historical development of the Square of Opposition, a collection of logical relationships traditionally embodied in a square diagram. This body of doctrine provided a foundation for work in logic for over two millenia. For most of this history, logicians assumed that negative particular propositions ("Some S is not P") are vacuously true if their subjects are empty. This validates the logical laws embodied in the diagram, and preserves the doctrine against modern criticisms. Certain additional principles ("contraposition" and "obversion") were sometimes adopted along with the Square, and they genuinely yielded inconsistency. By the nineteenth century an inconsistent set of doctrines was widely adopted. Strawson's 1952 attempt to rehabilitate the Square does not apply to the traditional doctrine; it does salvage the nineteenth century version but at the cost of yielding inferences that lead from truth to falsity when strung together.

Introduction

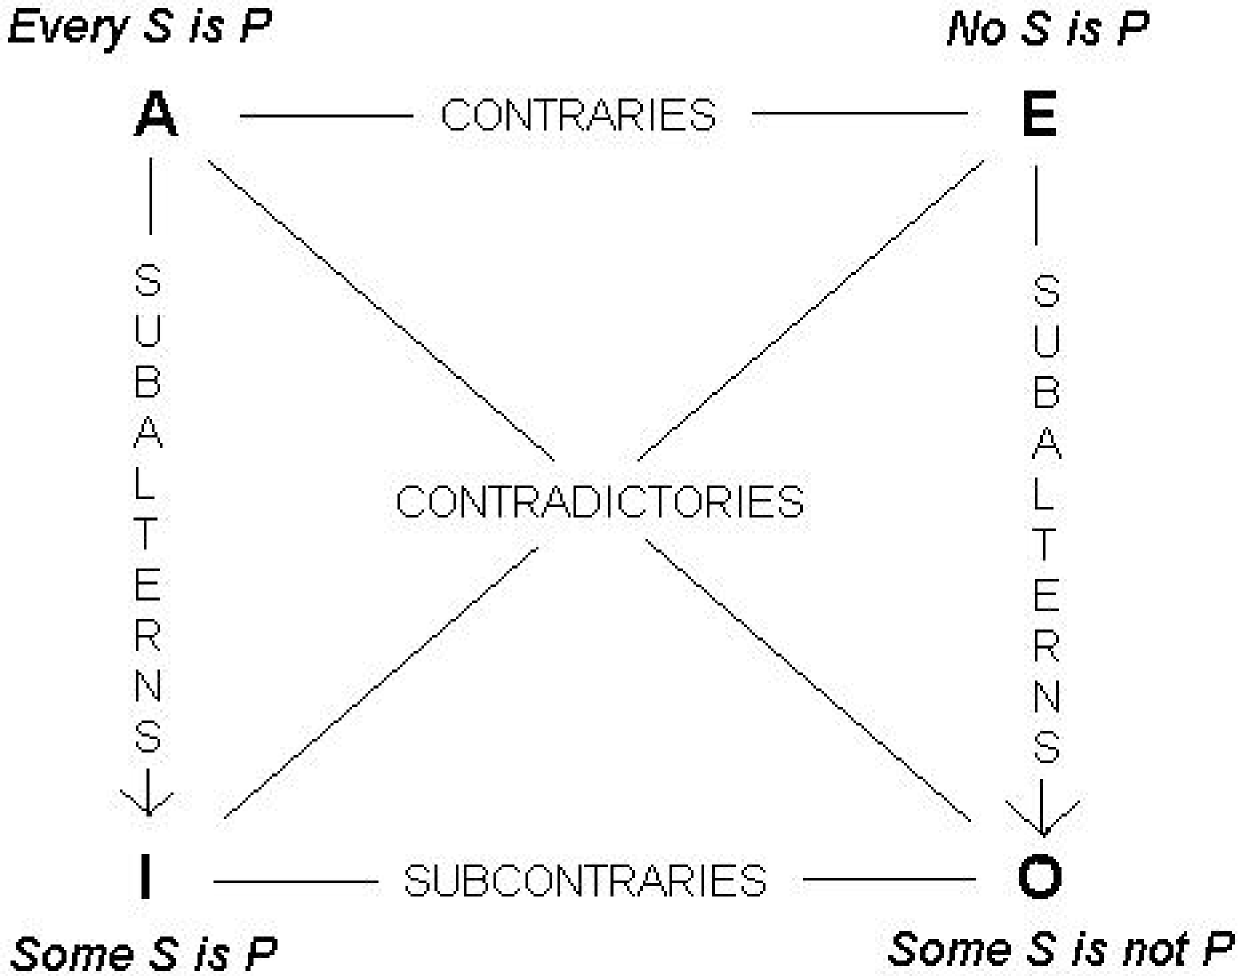
The doctrine of the square of opposition originated with Aristotle in the fourth century BC and has occurred in logic texts ever since. Although severely criticized in recent decades, it is still regularly referred to. The point of this entry is to trace its history from the vantage point of the end of the twentieth century, along with closely related doctrines bearing on empty terms.

The square of opposition is a group of theses embodied in a diagram. The diagram is not essential to the theses; it is just a useful way to keep them straight. The theses concern logical relations among four

logical forms:

NAME	*FORM*	*TITLE*
A	Every S is P	Universal Affirmative
E	No S is P	Universal Negative
I	Some S is P	Particular Affirmative
O	Some S is not P	Particular Negative

The diagram for the traditional square of opposition is:



The theses embodied in this diagram I call 'SQUARE'. They are:

SQUARE

- 'Every S is P' and 'Some S is not P' are contradictories.
- 'No S is P' and 'Some S is P' are contradictories.
- 'Every S is P' and 'No S is P' are contraries.

- ‘Some S is P’ and ‘Some S is not P’ are subcontraries.
- ‘Some S is P’ is a subaltern of ‘Every S is P’.
- ‘Some S is not P’ is a subaltern of ‘No S is P’.

These theses were supplemented with the following explanations:

- Two propositions are contradictory iff they cannot both be true and they cannot both be false.
- Two propositions are contraries iff they cannot both be true.
- Two propositions are subcontraries iff they cannot both be false.
- A proposition is a subaltern of another iff it must be true if its superaltern is true, and the superaltern must be false if the subaltern is false.

Probably nobody before the twentieth century every held exactly these views without holding certain closely linked ones as well. The most common closely linked view that is associated with the traditional diagram is that the E and I propositions *convert simply*; that is, ‘No S is P’ is equivalent in truth value to ‘No P is S’, and ‘Some S is P’ is equivalent in truth value to ‘Some P is S’. The traditional doctrine supplemented with simple conversion is a very natural view to discuss. It is Aristotle's view, and it was apparently endorsed (or at least not challenged) by everyone who wrote on this topic before the 19th century. I call this total body of doctrine ‘[SQUARE]’:

> [SQUARE] $=_{df}$ SQUARE + "the E and I forms convert simply"

where:

> A proposition *converts simply* iff it is necessarily equivalent in truth value to the proposition you get by interchanging its terms.

So [SQUARE] includes the relations illustrated in the diagram plus the view that ‘No S is P’ is equivalent to ‘No P is S’, and the view that ‘Some S is P’ is equivalent to ‘Some P is S’.

The Modern Revision of the Square

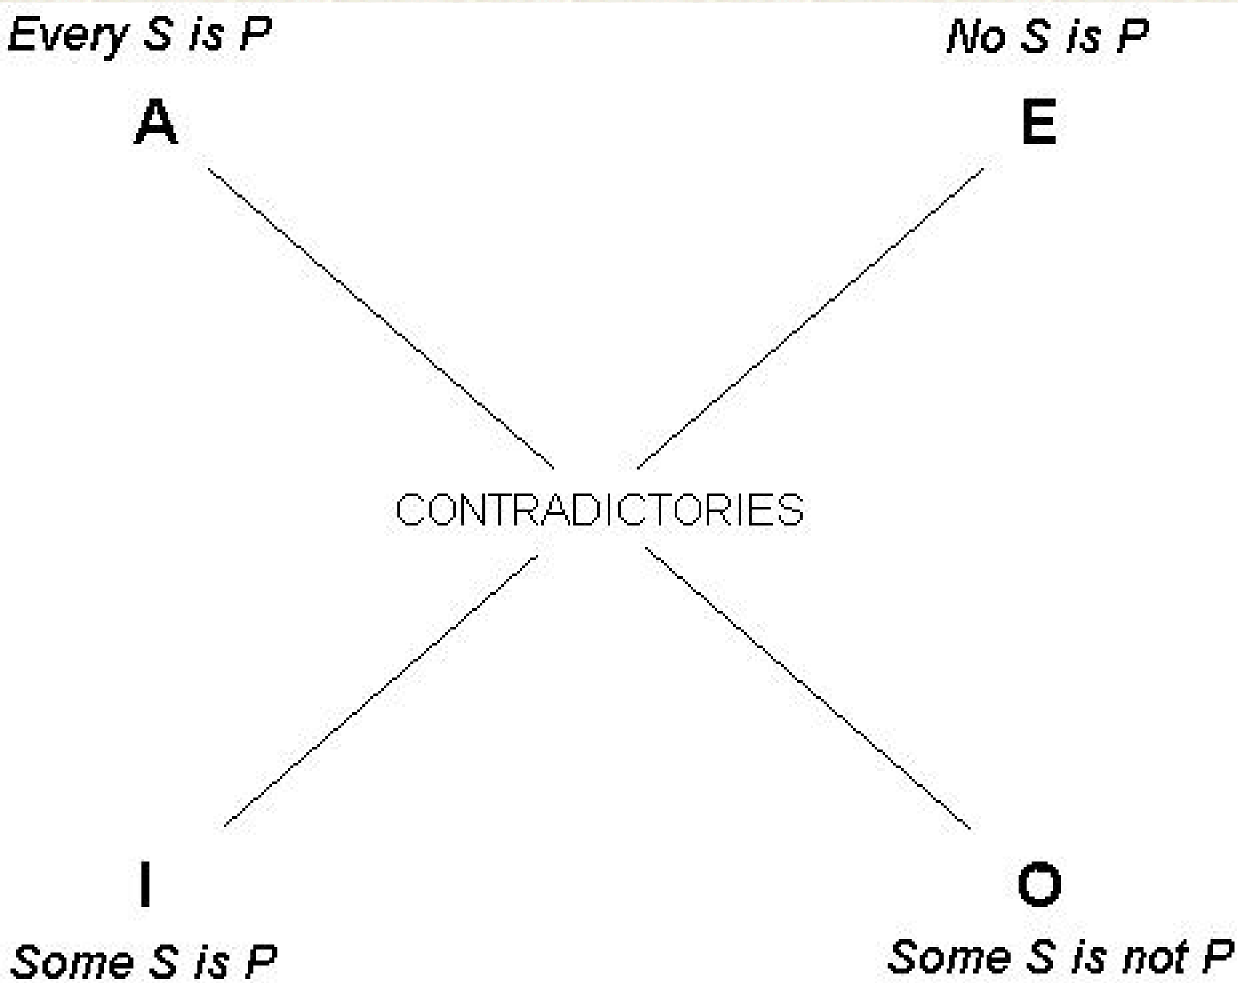
Most contemporary logic texts symbolize the traditional forms as follows:

Every S is P	$(x)(Sx \rightarrow Px)$
No S is P	$(x)(Sx \rightarrow -Px)$
Some S is P	$(\exists x)(Sx \& Px)$

Some S is not P (∃x)(Sx & -Px)

If this symbolization is adopted along with standard views about the logic of connectives and quantifiers, the relations embodied in the traditional square mostly disappear. The modern diagram looks like this:

THE MODERN REVISED SQUARE:



This has too little structure to be particularly useful, and so it is not commonly used. According to Alonzo Church, this modern view probably originated sometime in the late nineteenth century.[1] This representation of the four forms is now generally accepted, except for qualms about the loss of subalternation in the left-hand column. Most English speakers tend to understand ‘Every S is P’ as requiring for its truth that there be some S's, and if that requirement is imposed, then subalternation holds for affirmative propositions. Every modern logic text must address the apparent implausibility of letting ‘Every S is P’ be true when there are no S's. The common defense of this is usually that this is a logical notation devised for purposes of logic, and it does not claim to capture every nuance of the natural language forms that the symbols resemble. So perhaps ‘(x)(Sx → Px)’ does fail to do complete justice to ordinary usage of ‘Every S is P’, but this is not a problem with the logic. If you think that ‘Every S is P’ requires for its truth that there be S's, then you can have that result simply and easily: just represent the recalcitrant uses of ‘Every S is P’ in symbolic notation by adding an extra conjunct to the symbolization,

like this: (x)(Sx → Px) & (∃x) Sx.

This defense leaves logic intact and also meets the objection, which is not a logical objection, but merely a reservation about the representation of natural language.

Authors typically go on to explain that we often wish to make generalizations in science when we are unsure of whether or not they have instances, and sometimes even when we know they do not, and they sometimes use this as a defense of symbolizing the A form so as to allow it to be vacuously true. This is, however, an argument from convenience of notation, and does not bear on logical coherence.

The Argument Against the Traditional Square

Why does the traditional square need revising at all? The argument is a simple one:[2]

> Suppose that ‘S’ is an empty term; it is true of nothing. Then the I form: ‘Some S is P’ is false. But then its contradictory E form: ‘No S is P’ must be true. But then the subaltern O form: ‘Some S is not P’ must be true. But that is wrong, since there aren't any S's.

The puzzle about this argument is why the doctrine of the traditional square was maintained for well over 20 centuries in the face of this consideration. Were 20 centuries of logicians so obtuse as not to have noticed this apparently fatal flaw? Or is there some other explanation?

One possibility is that logicians previous to the 20th century must have thought that no terms are empty. You see this view referred to frequently as one that others held.[3] But with a few very special exceptions (discussed below) I have been unable to find anyone who held such a view before the nineteenth century. Many authors do not discuss empty terms, but those who do typically take their presence for granted. Explicitly rejecting empty terms was never a mainstream option, even in the nineteenth century.

In fact, the traditional doctrine of [SQUARE] is completely coherent in the presence of empty terms. This is because on the traditional interpretation, the O form lacks existential import. The O form is (vacuously) true if its subject term is empty, not false, and thus the logical interrelations of [SQUARE] are unobjectionable. In what follows, I trace the development of this view.

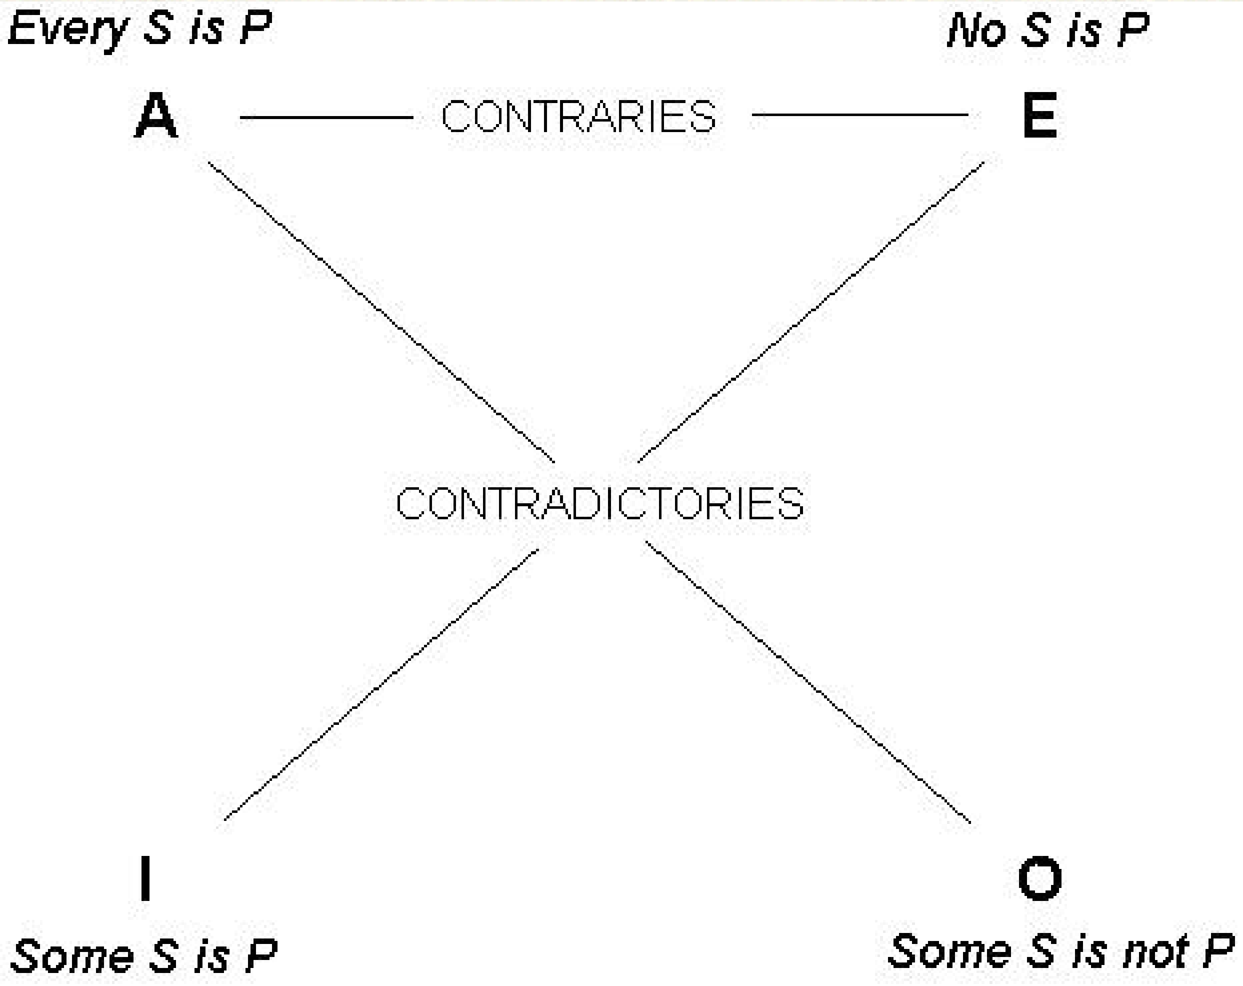
Origin of the Square of Opposition

The *doctrine* that I call [SQUARE], occurs in Aristotle. It begins in *De Interpretatione* 6-7, which contains three claims: that A and O are contradictories, that E and I are contradictories, and that A and E are contraries (17b.17-26):

> "I call an affirmation and a negation contradictory opposites when what one signifies universally the other signifies not universally, e.g. every man is white -- not every man is

> white, no man is white -- some man is white. But I call the universal affirmation and the universal negation contrary opposites, e.g. every man is just -- no man is just. So these cannot be true together, but their opposites may both be true with respect to the same thing, e.g. not every man is white -- some man is white."

This gives us the following fragment of the square:



But the rest is there by implication. For example, there is enough to show that I and O are subcontraries: they cannot both be false. For suppose that I is false. Then its contradictory, E, is true. So E's contrary, A, is false. So A's contradictory, O, is true. This refutes the possibility that I and O are both false, and thus fills in the bottom relation of subcontraries. Subalternation also follows. Suppose that the A form is true. Then its contrary E form must be false. But then the E form's contradictory, I, must be true. Thus if the A form is true, so must be the I form. A parallel argument establishes subalternation from I to O as well. The result is SQUARE.

In *Prior Analytics* I.2, 25a.1-25 we get the additional claims that the E and I propositions convert simply. Putting this together with the doctrine of *De Interpretatione* we have the full [SQUARE].[4]

The Diagram

The diagram accompanying and illustrating the doctrine shows up already in the second century A.D. Boethius incorporated it into his writing, and it passed down through the dark ages to the high medieval period, and from thence to today. Diagrams of this sort were popular among late classical and medieval authors, who used them for a variety of purposes. (Similar diagrams for modal propositions were especially popular.)

Aristotle's Formulation of the O Form

Ackrill's translation contains something a bit remarkable: Aristotle's articulation of the O form is *not* the familiar ‘Some S is not P’ or one of its variants; it is rather ‘Not every S is P’. With this wording, Aristotle's doctrine automatically escapes the modern criticism. (This holds for his views throughout *De Interpretatione*.[5]) For assume again that ‘S’ is an empty term, and suppose that this makes the I form ‘Some S is P’ false. Its contradictory, the E form: ‘No S is P’, is thus true, and this entails the O form in Aristotle's formulation: ‘Not every S is P’, which must therefore be true. When the O form was worded ‘Some S is not P’ this bothered us, but with it worded ‘Not every S is P’ it seems plainly right. Recall that we are granting that ‘Every S is P’ has existential import, and so if ‘S’ is empty the A form must be false. But then ‘Not every S is P’ *should* be true, as Aristotle's square requires.

On this view *affirmatives* have existential import, and *negatives* do not -- a point that became elevated to a general principle in late medieval times.[6] The ancients thus did not see the incoherence of the square as formulated by Aristotle because there was no incoherence to see.

The Rewording of the O Form

Aristotle's work was made available to the Latin west principally via Boethius's translations and commentaries, written a bit after 500 AD. In his translation of *De interpretatione*, Boethius preserves Aristotle's wording of the O form as "Not every man is white." But when Boethius comments on this text he illustrates Aristotle's doctrine with the now-famous diagram, and he uses the wording ‘Some man is not just’.[7] So this must have seemed to him to be a natural equivalent in Latin. It looks odd to us in English, but he wasn't bothered by it.

Early in the twelfth century Abelard objected to Boethius's rewording of the O form,[8] but Abelard's writing was not widely influential, and except for him and some of his followers people regularly used ‘Some S is not P’ for the O form in the diagram that represents the square. Did they allow the O form to be vacuously true? Perhaps we can get some clues to how medieval writers interpreted these forms by looking at other doctrines they endorsed. These are the theory of the syllogism and the doctrines of contraposition and obversion.

The (Ir)relevance of Syllogistic

One central concern of the Aristotelian tradition in logic is the theory of the categorical syllogism. This is the theory of two-premised arguments in which the premises and conclusion share three terms among them, with each proposition containing two of them. It is distinctive of this enterprise that everybody agrees on which syllogisms are valid. The theory of the syllogism partly constrains the interpretation of the forms. For example, it determines that the A form has existential import, at least if the O form does. For one of the valid patterns (Barbari[9]) is:

Every B is C

Every A is B

So, some A is C

This is invalid if the A form lacks existential import, and valid if it has existential import. It is held to be valid, and so we know how the A form is to be interpreted. One then naturally asks about the O form; what do the syllogisms tell us about it? The answer is that they tell us nothing beyond the fact that the O form is entailed by the E form. This lack of an answer is a fluke, resulting from the restrictions on what counts as a categorical syllogism; cases that would clearly decide the issue are not well-formed categorical syllogisms. At most, the theory confirms what we already know from SQUARE: that truth of the E form entails truth of the O form. And so if you are sure that the E form lacks such import, the O form must also lack it. Syllogistic gets us no further than this, though it does confirm that this body of theory nicely coheres with the lack of existential import of the O form.

The Principles of Contraposition and Obversion

One other piece of subject-matter bears on the interpretation of the O form. People were interested in Aristotle's discussion of "infinite" negation,[10] which is the use of negation to form a term from a term instead of a proposition from a proposition. In modern English we use ‘non’ for this; we make ‘non-horse’, which is true of exactly those things that are not horses. In medieval Latin ‘non-’ and ‘not’ are the same word, and so the distinction required special discussion. It became common to use infinite negation, and logicians pondered its logic. Some writers in the twelfth and thirteenth centuries adopted a principle called "conversion by contraposition." It states that

- ‘Every S is P’ is equivalent to ‘Every non-P is non-S’
- ‘Some S is not P’ is equivalent to ‘Some non-P is not non-S’

Unfortunately, this principle (which is not endorsed by Aristotle[11]) conflicts with the idea that there may be empty terms. For in the universal case it leads directly from the truth:

Every man is a being

to the falsehood:

Every non-being is a non-man

(which is false because the universal affirmative has existential import, and there are no non-beings). And in the particular case it leads from the truth (remember that the O form has no existential import):

A chimera is not a man.

to the falsehood:

A non-man is not a non-chimera.

These are Buridan's examples, used in the fourteenth century to show the invalidity of contraposition. Unfortunately, by Buridan's time the principle of contraposition had been advocated by a number of authors. The doctrine is already present in several twelfth century tracts,[12] and it is endorsed in the thirteenth century by Peter of Spain,[13] whose work was republished for centuries. William of Sherwood gives a counterexample to it, but then states confusingly that it holds in "every other case."[14] By the fourteenth century, problems associated with contraposition seem to be well-known, and authors generally cite the principle and note that it is not valid, but that it becomes valid with an additional assumption of existence of things falling under the subject term. For example, Paul of Venice in his eclectic and widely published *Logica Parva* from the end of the fourteenth century gives the traditional square with simple conversion[15] but rejects conversion by contraposition, essentially for Buridan's reason.

A similar thing happened with the principle of obversion. This is the principle that states that you can change a proposition from affirmative to negative, or vice versa, if you change the predicate term from finite to infinite (or infinite to finite). Some examples are:

Every S is P	=	No S is non-P
No S is P	=	Every S is non-P
Some S is P	=	Some S is not non-P
Some S is not P	=	Some S is non-P

Aristotle discussed some instances of obversion in *De Interpretatione*. It is apparent, given the truth conditions for the forms, that these inferences are valid when moving from affirmative to negative, but not in the reverse direction when the terms may be empty, as Buridan makes clear.[16] Some medieval writers before Buridan accepted the fallacious versions, and some did not.[17]

Later Developments

In Paul of Venice's other major work, the *Logica Magna* (*circa* 1400), he gives some pertinent examples of particular negative propositions that follow from true universal negatives. His examples of true particular negatives with patently empty subject terms are these:[18]

> *Some man who is a donkey is not a donkey.*
>
> *What is different from being is not.*
>
> *Some thing willed against by a chimera is not willed against by a chimera.*
>
> *A chimera does not exist.*
>
> *Some man whom a donkey has begotten is not his son.*

So by the end of the 14th century the problem of empty terms was clearly recognized. They were permitted in the theory, the O form definitely did not have existential import, and the logical theory, stripped of the incorrect special cases of contraposition and obversion, was coherent and immune to 20th century criticism.

Work on logic continued for the next couple of centuries, though most of it was lost and had little influence. But the topic of empty terms was squarely faced, and all solutions that were given within the Medieval tradition were consistent with [SQUARE]. I rely here on Ashworth 1974, 201-02, who reports the most common themes in the context of post-medieval discussions of contraposition. One theme is that contraposition is invalid when applied to universal or empty terms, for the sorts of reasons given by Buridan. The O form is explicitly held to lack existential import. A second theme, which Ashworth says was the most usual thing to say, is also found in Buridan: additional inferences, such as contraposition, become valid when supplemented by an additional premise asserting that the terms in question are non-empty.

An Oddity

There is one odd view that occurs at least twice, which may have as a consequence that there are no empty terms. In the thirteenth century, Lambert of Auxerre proposed that a term such as ‘chimera’ which stands for no existing thing must "revert to nonexistent things". So if we suppose that there no roses exist, then the term ‘rose’ stands for nonexistent things.[19] A related view also occurs much later; Ashworth reports that Menghus Blanchellus Faventinus held that term negations such as ‘nonman’ are true of non-beings, and he concluded from this that ‘A nonman is a chimera’ is true (apparently assuming that ‘chimera’ is also true of nonbeings).[20] However, neither of these views seems to have been clearly developed, and neither was widely adopted (or even widely discussed).[21] Nor is it even clear that either of them is supposed to have the consequence that there are no empty terms.

Modern, Renaissance, and Nineteenth Centuries

According to Ashworth,[22] serious and sophisticated investigation of logic ended at about the third decade of the sixteenth century. The *Port Royal Logic* of the following (seventeenth) century seems typical in its approach: its authors frequently suggest that logic is trivial and unimportant. Its doctrine includes that of the square of opposition, but the discussion of the O form is so vague that nobody could pin down its exact truth conditions, and there is certainly no awareness indicated of problems of existential import. This seems to typify popular texts for the next while. In the nineteenth century, the apparently most widely used textbook in Britain and America was Whately's *Elements of Logic*. Whately gives the traditional doctrine of the square, without any discussion of issues of existential import or of empty terms. He includes the problematic principles of contraposition (which he calls "conversion by negation"):

Every S is P	=	Every not-P is not-S
No S is P	=	No not-P is not-S

He also endorses obversion:[23]

- Some A is not B is equivalent to Some A is not-B, and thus it converts to Some not-B is A.

He says that this principle is "not found in Aldrich," but that it is "in frequent use."[24] This "frequent use" continued; later nineteenth and early twentieth century text books in England and America continued to endorse obversion (also called "infinitation" or "permutation"), and contraposition (also called "illative conversion").[25] This full nineteenth century tradition is consistent only on the assumption that empty (and universal) terms are prohibited, but authors seem unaware of this; Keynes 1928, 126, says generously "This assumption appears to have been made implicitly in the traditional treatment of logic." De Morgan is atypical in making the assumption explicit: in his 1847 text (64) he forbids universal terms (empty terms disappear by implication because if A is empty, non-A will be universal), and in his technical 1860 work he justifies this limitation on the grounds that universal terms are "needless" (16).[26]

In the twentieth century Lukasiewicz also developed a version of syllogistic that depends explicitly on the absence of empty terms; he attributed the system to Aristotle, thus helping to foster the tradition according to which the ancients were unaware of empty terms.

Today, logic texts divide between those based on contemporary logic and those from the Aristotelian tradition or the nineteenth century tradition, but even many texts that teach syllogistic teach it with the forms interpreted in the modern way, so that e.g. subalternation is lost. So the traditional square, as traditionally interpreted, is now mostly abandoned.

Strawson's Defense

In the twentieth century there were many creative uses of logical tools and techniques in reassessing past doctrines. One might naturally wonder if there is some ingenious interpretation of the square that attributes existential import to the O form *and* makes sense of it all without forbidding empty or universal terms, thus reconciling traditional doctrine with modern views. This is very close to what Strawson, 1952, 176-78, claims. Strawson's idea was to justify the square by adopting a nonclassical view of truth of statements, and by redefining the logical relation of validity. First, he suggested, we need to suppose that a proposition whose subject term is empty is neither true nor false, but lacks truth value altogether. Then we say that Q entails R just in case there are no instances of Q and R such that the instance of Q is true and the instance of R is false. For example, the A form ‘Every S is P’ entails the I form ‘Some S is P’ because there is no instance of the A form that is true when the corresponding instance of the I form is false. The troublesome cases involving empty terms turn out to be instances in which one or both forms lack truth value, and these are irrelevant so far as entailment is concerned. With this revised account of entailment, all of the "traditional" logical relations result, if they are worded as follows:

Contradictories:	The A and O forms entail each other's negations, as do the E and I forms. The negation of the A form entails the (unnegated) O form, and *vice versa*; likewise for the E and I forms.
Contraries: .	The A and E forms entail each other's negations
Subcontraries:	The negation of the I form entails the (unnegated) E form, and *vice versa*.
Subalternation:	The A form entails the I form, and the E form entails the O form.
Converses:	The E and I forms each entail their own converses.
Contraposition:	The A and O forms each entail their own contrapositives.
Obverses:	Each form entails its own obverse.

These doctrines are not, however, the doctrines of [SQUARE]. The doctrines of [SQUARE] are worded entirely in terms of the possibilities of truth values, not in terms of entailment. So "entailment" is irrelevant to [SQUARE]. It turns out that Strawson's revision of truth conditions *does* preserve the principles of SQUARE (these can easily be checked by cases),[27] but not the additional conversion principles of [SQUARE], and also not the traditional principles of contraposition or obversion. For example, Strawson's reinterpreted version of conversion holds for the I form because any I form proposition entails its own converse: if ‘Some A is B’ and ‘Some B is A’ both have truth value, then neither has an empty subject term, and so if neither lack truth value and if either is true the other will be true as well. But the original doctrine of conversion says that an I form and its converse always have the same truth value, and that is false on Strawson's account; if there are A's but no B's, then ‘Some A is B’ is false and ‘Some B is A’ has no truth value at all. Similar results follow for contraposition and obversion.

The "traditional logic" that Strawson discusses is much closer to that of nineteenth century logic texts than it is to the version that held sway for two millennia before that.[28] But even though he literally salvages a version of nineteenth century logic, the view he saves is unable to serve the purposes for which logical principles are formulated, as was pointed out by Timothy Smiley in a short note in *Mind* in 1967.[29] People have always taken the square to embody principles by which one can reason, and by which one can construct extended chains of reasoning. But if you string together Strawson's entailments you can infer falsehoods from truths, something that nobody in any tradition would consider legitimate. For example, begin with this truth (the subject term is non-empty):

> *No man is a chimera.*

By conversion, we get:

> *No chimera is a man.*

By obversion:

> *Every chimera is a non-man.*

By subalternation:

> *Some chimera is a non-man.*

By conversion:

> *Some non-man is a chimera.*

Since there are non-men, the conclusion is not truth-valueless, and since there are no chimeras it is false. Thus we have passed from a true claim to a false one. (The example does not even involve the problematic O form.) All steps are validated by Strawson's doctrine. So Strawson reaches his goal of preserving certain patterns commonly identified as constituting traditional logic, but at the cost of sacrificing the application of logic to extended reasoning.[30]

Notes to The Square of Opposition

Notes

1. Church 1965, 422 finds it first (implicitly) in Cayley 1871, explicitly in Brentano 1874, and in Peirce 1880, 15-57.

2. This argument is given e.g. in Kneale & Kneale 1962, 55-60.

3. Cf. Kneale & Kneale 1962, 60, and Keynes 1928, 126 note 1.

4. *Prior Analytics* also contains the doctrine of conversion *per accidens*: that you can interchange the subject and predicate terms of either universal form if you also turn it into a particular. This is not an additional principle, since it follows from the rules of subalternation together with simple conversion.

5. Cf. Wedin 1990.

6. Ockham (SL I.72): "In affirmative propositions a term is always asserted to supposit for something. Thus, if it supposits for nothing the proposition is false. However, in negative propositions the assertion is either that the term does not supposit for something or that it supposits for something of which the predicate is truly denied. Thus a negative proposition has two causes of truth." Loux 1974, 206.

7. Paul Spade called these facts to my attention.

8. Abelardus Petrus 1970, 186: "And thus in categorical propositions, the only proper and rightly destroying contradiction to any affirmation seems to be a proposition that with a negation appended in front destroys the entire meaning, so that ‘not every human is human’, but not ‘some human is not human’ is the contradictory of ‘every human is human’. For the latter may happen to be false simultaneously with that. For a thing of ‘human’ not existing now, neither will this be true, namely ‘every human is human’ nor that which says ‘some human is not human’ . . ."

9. Oddly, Aristotle does not mention this form, though it was accepted from the medieval period onward. (It is common to speculate that this form was too trivial to mention.) The same point can be made with a form he did discuss (Darapti): If every A is C and every A is B then some B is C.

10. Aristotle, *De Interpretatione* 2 and 3.

11. Church 1965, 419 quotes some apparent instances of contraposition endorsed by Aristotle. But the wordings he gives are not actually contraposition; their premises are apparently meant to be universal affirmatives (Every A is B) and their conclusions seem to be of a "nonstandard" negative form: Every non-B is not A. (Such conditionals, though not their converses, are valid.) These examples, however, might easily have been interpreted as contraposition by later commentators, just as Church did.

12. Contraposition is discussed in several twelfth and early thirteenth century anonymous texts edited in De Rijk 1967. It is endorsed in *Excerpta Norimbergenses* (138-39), *Ars Burana* (190), *Introductiones Parisienses* (362), *Logica "Ut dicit"* (385), *Logica "Cum sit nostra"* (426), *Dialectica Monacensis* (478). One text, *Tractatus Anagnini* (238) states contrapositions without making clear whether they are endorsed or not, though the context seems to suggest acceptance. But they are illustrated with what others took to be a counterexample to contraposition: "Every non-animal is a non-phoenix; so every phoenix is an animal". Another text, *Ars Emmerana* (157) endorses contraposition, but then says that it does not hold for the particular negative unless understood with "constancy," a term that had to do with assuming instances of the terms in question. One other text, *Introductiones Montane Minores* (34-35) straightforwardly objects to contraposition because of how it handles empty terms.

13. I.15 in Dineen 1990, 8.

14. 3.3 in Kretzmann 1966, 59.

15. 1.8-11 in Perreiah 1984, 127-130.

16. "From any affirmative there follows a negative by changing the predicate according to finite and infinite, keeping the rest the same, but there is no formal consequence from a negative to an affirmative, although there is a consequence under the assumption that all of the terms supposit for something." [*Tractatus de Consequentiis* I.8.107: King 1985, 226.]

The good direction he gives as:

> Every B is A; therefore no B is non-A.

The fallacious direction is illustrated by

> A chimera is not a man; therefore a chimera is a non-man.

17. Obversion is discussed in several twelfth and early thirteenth century anonymous texts edited in De Rijk 1967, where it is seen as a type of *equipollence*. It is endorsed in four of these: *Excerpta Norimbergenses* (138-39), *Logica "Ut dicit"* (385), *Logica "Cum sit nostra"* (426), *Dialectica Monacensis* (478). Three texts, *Ars Burana*, *Introductiones Parisienses*, *Tractatus Anagnini* omit it (while including a discussion of contraposition). One text, *Introductiones Montane Minores* (37-38)

objects to it because it mishandles empty terms.

18. Chapter 4 in Kretzmann 1979, 233.

19. Kretzmann & Stump 1988, 118.

20. Ashworth 1974, 201-02.

21. These odd views should not be confused with a widely adopted theory which held that in certain circumstances a term is "ampliated" so as to stand for not presently existing things. For example, the past tense of ‘A donkey ran’ makes ‘donkey’ stand for both present and past donkeys, the ‘can’ in ‘A rose can be red’ makes ‘rose’ stand for both actual and possible roses, and the special nature of the predicate in ‘A chimera is imaginable’ makes ‘chimera’ stand for (impossible but) merely intelligible chimeras. But this widely held doctrine does not apply to ‘A chimera is an animal’ since there is no "cause" of ampliation in that sentence; so the doctrine does not prohibit empty terms.

22. Ashworth 1978, 147.

23. Whately 1826, 84-85.

24. Whately 1827, 85. He apparently refers there to an earlier edition of Aldrich 1849.

25. Coppée 1882, 76, Jevons, 1888, 83-5, Davis, 1894, 91, Joseph, 1916, 237-38, R. W. Sellars, 1925, 107.

26. The system of logic including obversion and contraposition is consistent if empty and universal terms are forbidden; see Miller 1938. Miller states that if the system is supplemented by all of the traditional nineteenth century rules for the syllogism, including rules of distribution, the system is inconsistent. But his proof involves applying the rules of distribution to syllogisms that are not in standard form. Miller thinks that authors intended this, but I see no evidence of it.

27. The wording of SQUARE does not rule out the possibility of truth-valueless sentences -- so Strawson's view that empty subject terms lead to lack of truth value does not conflict with SQUARE. However, hardly anyone exploited the possibility of sentences without truth value. A few medieval writers appeared to have tried to solve the semantic paradoxes by holding that paradoxical sentences "say nothing", but the idea was not taken seriously by most theorists. (Cf. Spade's summary in Kretzmann, Kenny, and Pinborg 1982, 245-6.) Nor does it occur in Renaissance or Modern or nineteenth century texts.

Paul Spade points out (personal communication) that a very few authors held that future contingent

propositions are now without truth-value (and will stay that way until the future event comes out one way or the other). The most prominent mediaeval author to hold this was the Frenchman Peter Auriol (early 14th century). But the Englishman Roger Swyneshed (fl. 1330s) also appears to accept it in an offhand comment in one passage. Many authors (e.g., Ockham) thought it was Aristotle's view of future contingents (*De interpretation*, ch. 7), but did not accept it themselves.

28. Strawson 1952, 152 calls what he is discussing "traditional formal logic." His source is Miller 1938, which bears the title *The Structure of Aristotelian Logic*, which might lead one to think he is discussing the ancient and medieval doctrine. But Miller makes explicit (pages 11-12) that the subject matter under discussion is the version of logic that existed when he wrote: in particular, "the system of deductive logic expounded in the principal introductory textbooks of logic; for example, the well-known manuals by Whately, Jevons, Joseph, Wolf, Creighton, Hibbons, and Sellars." Miller's logical work is excellent, but his historical remarks should not be trusted. For example, he sees the use of the notion of distribution in testing for the validity of syllogisms as part of a longstanding tradition (6), followed by the introduction of negative terms in the nineteenth century (3). In fact negative terms were in the original theory (they were in Aristotle), and the use of rules of distribution to test for validity were probably first used seventeen centuries later (by Buridan in the fourteenth century; perhaps earlier, but certainly no earlier than the twelfth century).

29. Smiley 1967. Church 1965 also criticizes Strawson's proposal, but without actually saying what is wrong with it.

30. This entry is condensed from a longer version to appear in *Acta Analytica*.

Notes to Aristotle's Metaphysics

Notes

1. This crucial idea is put forward at *Posterior Analytics* 71b32; *Prior Analytics* 68b35-7; *Physics* A.1, 184a16-20; *Metaphysics* Z.3, 1029b3-12; *Topics* Z.4, 141b2-142a12.)

2. This inverse tree-like structure was first noticed in the 3rd century C.E. by Porphyry: “Substance is itself a genus, under this is body, and under body is living body, under which is animal. Under animal is rational animal, under which is man. Under man are Socrates and Plato and individual (*kata meros*) men” (*Isagoge* 4, 21-25). This so-called “tree of Porphyry” later found its way, with illustrations, into medieval discussions of Aristotle.

3. Although Aristotle himself never puts it this way, one might think of each category itself as a genus. This is certainly what Porphyry thought (see note 2). See also Owen 1965b. Note, however, that if a category is a genus, it is a maximally general one — it cannot be a species of some higher genus. For the union of all the categories contains everything that there is — i.e., all of the beings — and Aristotle insists that being is not a genus (*Posterior Analytics* 92b14, *Metaphysics* B.3, 998b22).

Aristotle's Rhetoric

Aristotle's rhetoric has had an enormous influence on the development of the art of rhetoric. Not only authors writing in the peripatetic tradition, but also the famous Roman teachers of rhetoric, such as Cicero and Quintilian, frequently used elements stemming from the Aristotelian doctrine. Nevertheless, these authors were neither interested in an authentic interpretation of the Aristotelian works nor in the philosophical sources and backgrounds of the vocabulary that Aristotle had introduced into rhetorical theory. Thus, for two millennia the interpretation of Aristotelian rhetoric has become a matter of the history of rhetoric, not of philosophy. In the most influential manuscripts and editions, Aristotle's *Rhetoric* was surrounded by rhetorical works and even written speeches of other Greek and Latin authors, and was seldom interpreted in the context of the whole Corpus Aristotelicum. It was not until the last few decades that the philosophically salient features of the Aristotelian rhetoric were rediscovered: in construing a general theory of the persuasive, Aristotle applies numerous concepts and arguments which are also treated in his logical, ethical, and psychological writings. His theory of rhetorical arguments, for example, is only one further application of his general doctrine of the *sullogismos*, which also forms the basis of dialectic, logic and his theory of demonstration. Another example is the concept of emotions: though emotions are one of the most important topics in the Aristotelian ethics, he nowhere offers such an illuminating account of single emotions as in the *Rhetoric*. Finally, it is the *Rhetoric* too which informs us about the cognitive features of language and style.

1. Works on Rhetoric

According to ancient testimonies, Aristotle wrote an early dialogue on rhetoric entitled '*Grullos*', in which he put forward the argument that rhetoric cannot be an art (*technê*); and since this is precisely the position of Plato's *Gorgias*, the lost dialogue *Grullos* has traditionally been regarded as a sign of Aristotle's (alleged) early Platonism. But the evidence for the position of this dialogue is too tenuous to support such strong conclusions: it also could have been a 'dialectical' dialogue, which listed the Pros and Cons of the thesis that rhetoric is an art. We do not know much more about the so-called '*Technê Sunagogê*', a collection of previous theories of rhetoric which is also ascribed to Aristotle. Cicero seems to use this collection itself, or at least a secondary source relying on it, as his main historical source when he gives a short survey of the history of pre-Aristotelian rhetoric in his *Brutus* 46-48. Finally, Aristotle once mentions a work called '*Theodecteia*' which has also been supposed to be Aristotelian; but more probably he meant the rhetorical handbook of his follower Theodectes, who was a former pupil of Isocrates.

What has come down to us are just the three books on rhetoric, which we know as *The Rhetoric*, though the ancient catalogue of the Aristotelian works, reported by Diogenes Laertius, mentions only two books on rhetoric (perhaps our *Rhetoric* I & II), and two further books on style (perhaps our *Rhetoric* III?). Whereas most modern authors agree that at least the core of *Rhet.* I & II presents a coherent rhetorical theory, the two themes of *Rhet.* III are not mentioned in the agenda of *Rhet.* I & II. The conceptual link between *Rhet.* I & II and *Rhet.* III is not given until the very last sentence of the second book. It is quite understandable that the authenticity of this *ad hoc* composition has been questioned: we cannot exclude the possibility that these two parts of the *Rhetoric* had not been put together until the first edition of Aristotle's works completed by Andronicus in the first century. In the *Poetics* (1456a33) we find a cross-reference to a work called '*Rhetoric*' which obviously refers to *Rhet.* I & II, but excludes *Rhet.* III.

Regardless of such doubts, the systematic idea which links the two heterogeneous parts of the *Rhetoric* together does not at all seem to be unreasonable : it is not enough to have a supply of things to say (the so-called “thought”), the theorist of rhetoric must also inform us about the right way to say those things (the so-called “style”).

The chronological fixing of the *Rhetoric* has turned out to be a delicate matter. At least the core of *Rhet.* I & II seems to be an early work, written during Aristotle's first stay in Athens (it is unclear, however, which chapters belong to that core; regularly mentioned are the chapters I.4-15 and II.1-17). It is true that the *Rhetoric* gives references to historical events which fall in the time of Aristotle's exile and his second stay in Athens, but most of them can be found in the chapters II.23-24, and besides this, examples could have been updated, which is especially plausible if we assume that the *Rhetoric* formed the basis of a lecture held several times. Most striking are the affinities to the (also early) *Topics*; if, as it is widely agreed, the *Topics* represents a pre-syllogistic state of Aristotelian logic, the same is true of the *Rhetoric*: we actually find no hints of syllogistic inventory in it.

2. The Agenda of the *Rhetoric*

The structure of *Rhet.* I & II is determined by two tripartite divisions. The first division consists in the distinction of the three means of persuasion: The speech can produce persuasion either through the character of the speaker, the emotional state of the listener, or the argument (*logos*) itself (see below §5). The second tripartite division concerns the three species of public speech. The speech that takes place in the assembly is defined as the deliberative species. In this rhetorical species the speaker either advises the audience to do something or warns against doing something. Accordingly, the audience has to judge things that are going to happen in the future, and they have to decide whether these future events are good or bad for the polis, whether they will cause advantage or harm. The speech that takes place before a court is defined as the judicial species. The speaker either accuses somebody or defends herself or someone else. Naturally, this kind of speech treats things that happened in the past. The audience or rather jury has to judge whether a past event was just or unjust, i.e. whether it was according to the law or contrary to the law. While the deliberative and judicial species have their context in a controversial situation in which the listener has to decide in favor of one of two opposing parties, the third species does not aim at such a decision: the epideictic speech praises or blames somebody, it tries to describe things or deeds of the respective person as honorable or shameful.

The first book of the *Rhetoric* treats the three species in succession. *Rhet.* I.4-8 deals with the deliberative, I.9 with the epideictic, I.10-14 the judicial species. These chapters are understood as contributing to the argumentative mode of persuasion or—more precisely—to that part of argumentative persuasion which is specific to the several species of persuasion. The second part of the argumentative persuasion which is common to all three species of rhetorical speech is treated in the chapters II.19-26. The second means of persuasion, which works by evoking the emotions of the audience, is described in the chapters II.2-11. Though the following chapters II.12-17 treat of different types of character these chapters do not, as is often assumed, develop the third means of persuasion, which depends on the character of the speaker. The underlying theory of this means of persuasion is elaborated in a few lines of chapter II.1. The

aforementioned chapters II.12-17 give information about different types of character and their disposition to emotional response, which can be useful for those speakers who want to arouse the emotions of the audience. Why the chapters on the argumentative means of persuasion are separated by the treatment of emotions and character (in II.2-17) remains a riddle, especially since the chapter II.18 tries to give a link between the specific and the common aspects of argumentative persuasion. *Rhetoric* III.1-12 discusses several questions of style (see below §8.1), Rhetoric III.13-19 is on the several parts of a speech.

3. Rhetoric as a Counterpart to Dialectic

Aristotle stresses that rhetoric is closely related to dialectic. He offers several formulas to describe this affinity between the two disciplines: first of all, rhetoric is said to be a “counterpart” (*antistrophos*) to dialectic (*Rhet.* I.1, 1354a1); (ii) it is also called an “outgrowth” (*paraphues ti*) of dialectic and the study of character (*Rhet.* I.2, 1356a25f.); finally, Aristotle says that rhetoric is part of dialectic and resembles it (*Rhet.* I.2, 1356a30f.). In saying that rhetoric is a counterpart to dialectic Aristotle obviously alludes to Plato's *Gorgias* (464bff.) where rhetoric is ironically defined as a counterpart to cookery in the soul. Since, in this passage, Plato uses the word ‘*antistrophos*’ to designate an analogy, it is likely that Aristotle wants to express a kind of analogy too: what dialectic is for the (private or academic) practice of attacking and maintaining an argument, rhetoric is for the (public) practice of defending oneself or accusing an opponent.

This analogy between rhetoric and dialectic can be substantiated by several common features of both disciplines:

- Rhetoric and dialectic are concerned with things that do not belong to a definite genus or are not the object of a specific science.
- Rhetoric and dialectic rely on accepted sentences (*endoxa*).
- Rhetoric and dialectic are not dependent on the principles of certain sciences.
- Rhetoric and dialectic are concerned with both sides of an opposition.
- Rhetoric and dialectic rely on the same theory of deduction and induction.
- Rhetoric and dialectic similarly apply the so-called *topoi*.

The analogy to dialectic has important implications for the status of rhetoric. Plato argued in his *Gorgias* that rhetoric cannot be an art (*technê*), since it is not related to a definite subject, while real arts are defined by their specific subjects, as e.g. medicine or shoemaking are defined by their products, i.e. health and shoes. However, though dialectic has no definite subject, it is easy to see that it nevertheless rests on a method, because dialectic has to grasp the reason why some arguments are valid and others are not. Now, if rhetoric is nothing but the counterpart to dialectic in the domain of public speech, it must be grounded on an investigation of what is persuasive and what is not, and this, in turn, qualifies rhetoric as an art.

Further, it is central for both disciplines that they deal with arguments from accepted premises. Hence the rhetorician who wants to persuade by arguments or (rhetorical) proofs can adapt most of the dialectical equipment. Nevertheless, persuasion which takes place before a public audience is *not only* a matter of

arguments and proofs, but also of credibility and emotional attitudes. This is why there are remarkable differences between the two disciplines too:

- Dialectic can be applied to every object whatsoever, rhetoric is useful especially in practical and public matters.
- Dialectic proceeds by questioning and answering, while rhetoric for the most part proceeds in continuous form.
- Dialectic is concerned with general questions, while rhetoric is concerned for the most part with particular topics (i.e. things about which we cannot gain real knowledge).
- Certain uses of dialectic apply qualified *endoxa*, i.e. *endoxa* which are approved by experts, while rhetoric aims at *endoxa* which are popular.
- Rhetoric must take into account that its target group has only restricted intellectual resources, whereas such concerns are totally absent from dialectic.
- While dialectic tries to test the consistency of a set of sentences, rhetoric tries to achieve the persuasion of a given audience.
- Non-argumentative methods are absent from dialectic, while rhetoric uses non-argumentative means of persuasion.

4. The Purpose of Rhetoric

4.1 The Definition of Rhetoric

Aristotle defines the rhetorician as someone who is always able to see what is persuasive (*Topics* VI.12, 149b25). Correspondingly, rhetoric is defined as the ability to see what is possibly persuasive in every given case (*Rhet.* I.2, 1355b26f.). This is not to say that the rhetorician will be able to convince under all circumstances. Rather he is in a similar situation as the physician: the latter has a complete grasp of his art only if he neglects nothing which might heal his patient, though he is not able to heal *every* patient. Similarly, the rhetorician has a complete grasp of his method, if he discovers the available means of persuasion, though he is not able to convince *everybody*.

4.2 The Neutrality of Aristotelian Rhetoric

Aristotelian rhetoric as such is a neutral tool that can be used by persons of virtuous or depraved character. This capacity can be used for good or bad purposes, it can cause great benefits as well as great harms. There is no doubt that Aristotle himself regards his system of rhetoric as something useful, but the good purposes for which rhetoric is useful do not define the rhetorical capacity as such. Thus, Aristotle does not hesitate to concede on the one hand that his art of rhetoric can be misused. But on the other hand he tones down the risk of misuse by stressing several factors: Generally, it is true of all goods, except virtue, that they can be misused. Secondly, using rhetoric of the Aristotelian style it is easier to convince of the just and good than of their opposites. Finally, the risk of misuse is compensated by the benefits which can be accomplished by rhetoric of the Aristotelian style.

4.3 Why We Need Rhetoric

It could still be objected that rhetoric is only useful for those who want to outwit their audience and conceal their real aims, since someone who just wants to communicate the truth could be straightforward and would not need rhetorical tools. This, however, is not Aristotle's point of view: Even those who just try to establish what is just and true need the help of rhetoric when they are faced with a public audience. Aristotle tells us, that it is impossible to teach such an audience, even if the speaker had the most exact knowledge of the subject. Obviously he thinks that the audience of a public speech consists of ordinary people who are not able to follow an exact proof based on the principles of a science. Further, such an audience can easily be distracted by factors which do not pertain to the subject at all; sometimes they are receptive to flattery or just try to increase their own advantage. And this situation even becomes worse if the constitution, the laws, and the rhetorical habits in a city are bad. Finally, most of the topics that are usually discussed in public speeches do not allow of exact knowledge, but leave room for doubt; especially in such cases it is important that the speaker seems to be a credible person and that the audience is in a sympathetic mood. For all those reasons it is a matter of persuasiveness, not of knowledge, to affect the decisions of juries and assemblies. It is true that some people manage to be persuasive either at random or by habit, but it is rhetoric which gives us a method to discover *all* means of persuasion on *any* topic whatsoever.

4.4 Aristotelian Rhetoric as Proof-centered and Pertinent

Aristotle joins Plato in criticizing contemporary manuals of rhetoric. But how does he manage to distinguish his own project over and against the criticized manuals? The general idea seems to be this: Previous theorists of rhetoric gave most of their attention to methods outside the subject; they taught how to slander, how to arouse emotions in the audience, or how to distract the attention of the hearers from the subject. This style of rhetoric promotes a situation in which juries and assemblies no longer form rational judgments about the given issues but surrender to the litigants. Aristotelian rhetoric is different in this respect: it is centered around the rhetorical kind of proof, the enthymeme (see below §6), which is called the most important means of persuasion. Since people are most strongly convinced when they suppose that something has been proven (*Rhet.* I.1, 1355a5f.), there is no need for the orator to confuse or distract the audience by the use of emotional appeals etc. In Aristotle's view an orator will be even more successful when he just picks up the convincing aspects of a given issue, thereby using commonly held opinions as premises. Since people have a natural disposition for the true (*Rhet.* I.1, 1355a15f.) and every man has some contribution to make to the truth (*Eudemian Ethics* I.6, 1216b31) there is no unbridgeable gap between the commonly held opinions and what is true. This alleged affinity between the true and the persuasive justifies Aristotle's project of a rhetoric which essentially relies on the persuasiveness of pertinent argumentation; and it is just this argumentative character of Aristotelian rhetoric that explains the close affinity between rhetoric and dialectic (see above §3).

4.5 Is There an Inconsistency in Aristotle's Rhetorical Theory?

Of course, Aristotle's rhetoric covers non-argumentative tools of persuasion as well. He tells the orator how to stimulate emotions and how to make himself credible (see below §5); his art of rhetoric includes considerations about delivery and style (see below §8.1) and the parts of a speech. It is understandable that several interpreters found an insoluble tension between the argumentative means of pertinent rhetoric and non-argumentative tools which aims at what is outside the subject. It does not seem, however, that Aristotle himself saw a major conflict between these diverse tools of persuasion. Presumably, for the following reasons: (i) He leaves no doubt that the subject that is treated in a speech has the highest priority (e.g. *Rhet.* III.1, 1403b18-27). Thus, it is not surprising that there are even passages which regard the non-argumentative tools as a sort of accidental contribution to the process of persuasion which essentially proceeds in the manner of dialectic (cp. *Rhet.* I.1, 1354a15). (ii) There are, he says (III.1, 1404a2f.) methods which are not right, but necessary because of certain deficiencies of the audience. His point seems to be that the argumentative method becomes less effective, the worse the condition of the audience is. This again is to say that it is due to the badness of the audience when his rhetoric includes aspects which are not in line with the idea of argumentative and pertinent rhetoric. (iii) In dealing with methods of traditional rhetoric Aristotle obviously assumes that even methods which have traditionally been used instead of argumentation can be refined so that they support the aim of an argumentative style of rhetoric. The prologue of a speech, for example, was traditionally used for appeals to the hearer, but it can also be used to set out the issue of the speech, thus contributing to its clearness. Similarly, the epilogue has traditionally been used to arouse emotions like pity or anger; but as soon as the epilogue recalls the conclusions reached, it will make the speech more understandable.

5. The Three Means of Persuasion

The systematical core of Aristotle's *Rhetoric* is the doctrine that there are three technical means of persuasion. The attribute “technical” implies two characteristics: (i) Technical persuasion must rest on a method, and this, in turn, is to say that we must know the reason why some things are persuasive and some are not. Further, methodical persuasion must rest on a complete analysis of what it means to be persuasive. (ii) Technical means of persuasion must be provided by the speaker himself, whereas preexisting facts, such as oaths, witnesses, testimonies, etc. are non-technical, since they cannot be prepared by the speaker.

A speech consists of three things: the speaker, the subject which is treated in the speech, and the hearer to whom the speech is addressed (*Rhet.* I.3, 1358a37ff.). It seems that this reason why only three technical means of persuasion are possible: Technical means of persuasion are either (a) in the character of the speaker, or (b) in the emotional state of the hearer, or (c) in the argument (*logos*) itself.

(a) The persuasion is accomplished by character whenever the speech is held in such a way as to render the speaker worthy of credence. If the speaker appears to be credible, the audience will form the second order judgment that propositions put forward by the credible speaker are true or acceptable. This is especially important in cases where there is no exact knowledge but room for doubt. But how does the speaker manage to appear as a credible person? He must display (i) practical intelligence (*phronêsis*), (ii) a virtuous character, and (iii) good will (*Rhet.* II.1, 1378a6ff.); for, if he displayed none of them, the

audience would doubt that he is able to give good advices at all. Again, if he displayed (i) without (ii) and (iii), the audience could doubt whether the aims of the speaker are good. Finally, if he displayed (i) and (ii) without (iii), the audience could still doubt whether the speaker gives the best suggestion, though he knows what it is. But if he displays all of them, Aristotle concludes, it cannot rationally be doubted that his suggestions are credible. It must be stressed that the speaker must accomplish these effects by *what* he says; it is not necessary that he is actually virtuous: on the contrary, a preexisting good character cannot be part of the technical means of persuasion.

(b) The success of the persuasive efforts depends on the emotional dispositions of the audience; for we do not judge in the same way when we grieve and rejoice or when we are friendly and hostile. Thus, the orator has to arouse emotions exactly because emotions have the power to modify our judgments: to a judge who is in a friendly mood, the person about whom he is going to judge seems not to do wrong or only in a small way; but to the judge who is in an angry mood, the same person will seem to do the opposite (cp. *Rhet.* II.1, 1378a1ff.). Many interpreters writing on the rhetorical emotions were misled by the role of the emotions in Aristotle's ethics: they suggested that the orator has to arouse the emotions in order (i) to motivate the audience or (ii) to make them better persons (since Aristotle requires that virtuous persons do the right things together with the right emotions). Thesis (i) is false for the simple reason that the aim of rhetorical persuasion is a certain judgment (*krisis*), not an action or practical decision (*prohairesis*). Thesis (ii) is false, because moral education is not the purpose of rhetoric (see above §4), nor could it be effected by a public speech: “Now if speeches were in themselves enough to make men good, they would justly, as Theognis says, have won very great rewards, and such rewards should have been provided; but as things are …. they are not able to encourage the many to nobility and goodness.” (EN X.9. 1179b4-10)

How is it possible for the orator to bring the audience to a certain emotion? Aristotle's technique essentially rests on the knowledge of the definition of every significant emotion. Let, for example, anger be defined as “desire, accompanied with pain, for conspicuous revenge for a conspicuous slight that was directed against oneself or those near to one, when such a slight is undeserved.” (Rhet. II.2 1378a31-33). According to such definitions, someone who believes that he has suffered a slight from a person, who is not entitled to do so, etc., will become angry. If we take such a definition for granted, it is possible to deduce circumstances in which a person will most probably be angry; for example, we can deduce (i) in what state of mind people are angry and (ii) against whom they are angry and (iii) for what sorts of reason. Aristotle deduces these three factors for several emotions in the chapters II.2-11. With this equipment the orator will be able, for example, to highlight such characteristics of a case which are likely to provoke anger in the audience. In comparison with the tricks of former rhetoricians this method of arousing emotions has a striking advantage: The orator who wants to arouse emotions must not even speak outside the subject; it is sufficient to detect aspects of a given subject which are causally connected with the intended emotion.

(c) We persuade by the argument itself when we demonstrate or seem to demonstrate that something is the case. For Aristotle, there are two species of arguments: inductions and deductions (*Posterior Analytics* I.1, 71a5ff.). Induction (*epagôgê*) is defined as the proceeding from particulars up to a universal (*Topics* I.12, 105a13ff.). A deduction (*sullogismos*) is an argument in which, certain things having been supposed,

something different from the suppositions results of necessity through them (*Topics* I.1, 100a25ff.) or because of their being true (*Prior Analytics* I.2, 24b18-20). The inductive argument in rhetoric is the example (*paradeigma*); as opposed to other inductive arguments it does not proceed from many particular cases to one universal case, but from one particular to a similar particular if both particulars fall under the same genus (*Rhet.* I.2, 1357b25ff.). The deductive argument in rhetoric is the enthymeme (see below §6):

> but when, certain things being the case, something different results, beside them because of their being true, *either universally or for the most part*, it is called deduction here (in dialectic) and enthymeme there (in rhetoric).

It is remarkable that Aristotle uses the qualification "either universally or for the most part": obviously, he wants to say that in some cases the conclusion follows universally, i.e. by necessity, while in other cases it follows only *for the most part*. At first glance, this seems to be inconsistent, since a non-necessary inference is no longer a deduction. However, it has been disputed whether in arguments from probable premises the formula "for the most part" qualifies the inference itself ("If for the most part such and such is the case *it follows for the most part* that something different is the case"), or only the conclusion ("If for the most part such and such is the case *it follows by necessity* that *for the most part* something different is the case"). If the former interpretation is true, then Aristotle concedes in the very definition of the enthymeme that some enthymemes are not deductive. But if the latter interpretation (which has a parallel in *An. post.* 87b23-25) is correct, an enthymeme whose premises and conclusion are for the most part true would still be a valid deduction.

6. The Enthymeme

6.1 The Concept of Enthymeme

For Aristotle, an enthymeme is what has the function of a proof or demonstration in the domain of public speech. Since a demonstration is a kind of *sullogismos*, and the enthymeme is said to be a *sullogismos* too. The word '*enthymeme*' (from '*enthumeisthai* - to consider') had already been coined by Aristotle's predecessors and originally designated clever sayings, bon mots and short arguments involving a paradox or contradiction. The concepts 'proof' (*apodeixis*) and '*sullogismos*' play a crucial role in Aristotle's logical-dialectical theory. In applying them to a term of conventional rhetoric Aristotle appeals to a well known rhetorical technique, but, at the same time, restricts and codifies the original meaning of 'enthymeme': properly understood, what people call 'enthymeme' *should* have the form of a *sullogismos*, i.e. a deductive argument.

6.2 Formal Requirements

In general, Aristotle regards deductive arguments as a set of sentences in which some sentences are premises and one is the conclusion, and the inference from the premises to the conclusion is guaranteed by the premises alone. Since enthymemes in the proper sense are expected to be deductive arguments, the

minimal requirement for the formulation of enthymemes is that they have to display the premise-conclusion-structure of deductive arguments. This is why enthymemes have to include a statement as well as a kind of reason for the given statement. Typically this reason is given in a conditional ‘if’-clause or a causal ‘since’- or ‘for’-clause. Examples of the former , conditional type are: “If not even the gods know everything, human beings can hardly do so.” “If the war is the cause of present evils, things should be set right by making peace.” Examples of the latter, causal type are: “One should not be educated, for one ought not be envied (and educated people are usually envied).” “She has given birth, for she has milk.” Aristotle stresses that the sentence “There is no man among us who is free” taken for itself is a maxim, but becomes an enthymeme as soon as it is used together with a reason such as “for all are slaves of money or of chance (and no slave of money or chance is free).” Sometimes the required reason may even be implicit, as e.g. in the sentence “As a mortal do not cherish immortal anger” the reason why one should not cherish mortal anger is implicitly given in the phrase “immortal,” which alludes to the rule that is not appropriate for mortal beings to have such an attitude.

6.3 Enthymemes as Dialectical Arguments

Aristotle calls the enthymeme the “body of persuasion,” implying that everything else is only an addition or accident to the core of the persuasive process. The reason why the enthymeme as the rhetorical kind of proof or demonstration should be regarded as central for the rhetorical process of persuasion is that we are most easily persuaded when we think that something has been demonstrated. Hence, the basic idea of a rhetorical demonstration seems to be this: In order to make a target group believe that q, the orator must first select a sentence p or some sentences $p_1 \ldots p_n$ that are already accepted by the target group, secondly she has to show that q can be derived from p or $p_1 \ldots p_n$, using p or $p_1 \ldots p_n$ as premises. Given that the target persons form their beliefs in accordance with rational standards, they will accept q as soon as they understand that q can be demonstrated on the basis of their own opinions.

Consequently, the construction of enthymemes is primarily a matter of deducing from accepted opinions (*endoxa*). Of course, it is also possible to use premises which are not commonly accepted by themselves, but can be derived from commonly accepted opinions; other premises are only accepted since the speaker is held to be credible; still other enthymemes are built from signs: see §6.5. That a deduction is made from accepted opinions—as opposed to deductions from first and true sentences or principles—is the defining feature of dialectical argumentation in the Aristotelian sense. Thus, the formulation of enthymemes is a matter of dialectic, and the dialectician has the competence that is needed for the construction of enthymemes. If enthymemes are a subclass of dialectical arguments then, it is natural to expect a specific difference by which one can tell enthymemes apart from all other kinds of dialectical arguments (traditionally, commentators regarded logical incompleteness as such a difference; for some objections against the traditional view see §6.4). Nevertheless, this expectation is somehow misled: The enthymeme is different from other kinds of dialectical arguments, insofar as it is used in the rhetorical context of public speech (and rhetorical arguments are called ‘enthymemes’); thus, no further formal or qualitative differences are needed.

However, in the rhetorical context there are two factors that the dialectician has to keep in mind if she

wants to become a rhetorician too, and if the dialectical argument is to become a successful enthymeme. Firstly, the typical subjects of public speech do not - as the subject of dialectic and theoretical philosophy - belong to the things that are necessarily the case, but are among those things which are the goal of practical deliberation and can also be otherwise. Secondly, as opposed to well trained dialecticians the audience of public speech is characterized by an intellectual insufficiency; above all, the member of a jury or assembly are not accustomed to follow a longer chain of inferences. Therefore enthymemes must not be as precise as a scientific demonstration and should be shorter than ordinary dialectical arguments. This, however, is not to say that the enthymeme is defined by incompleteness and brevity. Rather, it is a sign of a well executed enthymeme that the content and the number of its premises are adjusted to the intellectual capacities of the public audience; but even an enthymeme which failed to incorporate these qualities would still be enthymeme.

6.4 The Brevity of the Enthymeme

In a well known passage (*Rhet.* I.2, 1357a7-18; similar: *Rhet.* II.22, 1395b24-26) Aristotle says that the enthymeme often has few or even fewer premises than some other deductions, (*sullogismoi)*. Since most interpreters refer the word '*sullogismos*' to the syllogistic theory (see the entry on Aristotle's logic) according to which a proper deduction has exactly two premises, those lines have led to the wide spread understanding that Aristotle defines the enthymeme as a *sullogismos* in which one of two premises has been suppressed, i.e. as an abbreviated, incomplete syllogism. But certainly the mentioned passages do not attempt to give a definition of the enthymeme, nor does the word '*sullogismos*' necessarily refer to deductions with exactly two premises. Properly understood, both passages are about the selection of appropriate premises, not about logical incompleteness. The remark that enthymemes often have few or less premises concludes the discussion of two possible mistakes the orator could make (Rhet. I.2, 1357a7-10): One can draw conclusions from things that have previously been deduced or from things that have not been deduced yet. The latter method is unpersuasive, for the premises are not accepted nor have they been introduced. The former method is problematic too: if the orator has to introduce the needed premises by another deduction, and the premises of this pre-deduction too, etc., one will end up with a long chain of deductions. Arguments with several deductive steps are common in dialectical practice, but one cannot expect the audience of a public speech to follow such long arguments. This is why Aristotle says that the enthymeme is and should be from fewer premises.

Supplement on The Brevity of the Enthymeme

6.5 Different Types of Enthymemes

Just as there is a difference between real and apparent or fallacious deductions in dialectic, we have to distinguish between real and apparent or fallacious enthymemes in rhetoric. The *topoi* for real enthymemes are given in chapter II.23, for fallacious enthymemes in chapter II.24. The fallacious enthymeme pretends to include a valid deduction, while it actually rests on a fallacious inference.

Further, Aristotle distinguishes between enthymemes taken from probable (*eikos*) premises and

enthymemes taken from signs (*sêmeia*). (Rhet. I.2, 1357a32-33). In a different context he says that enthymemes are based on probabilities, examples, *tekmêria* (i.e. proofs, evidences), and signs (Rhet. II.25, 1402b12-14). Since the so-called *tekmêria* are a subclass of signs and the examples are used to establish general premises, this is only an extension of the former classification. (Note that both classifications do not interfere with the idea that premises have to be accepted opinions: with respect to the signs the audience must *believe* that they exist and *accept* that they indicate the existence of something else, and with respect to the probabilities people must *accept* that something is likely to happen.)However, it is not clear whether this is meant to be an exhaustive typology. That most of the rhetorical arguments are taken from probable premises (“For the most part it is true that …,” “It is likely that …”), is due to the typical subjects of public speech, which are rarely necessary. When using a sign-argument or sign-enthymeme we do not try to explain a given fact; we just indicate, *that* something exists or is the case: “… anything such that when it is another thing is, or when it has come into being the other has come into being before or after, is a sign of the other's being or having come into being.” (*Prior Analytics* II.27, 70a7ff.). But there are several types of sign-arguments too; Aristotle offers the following examples:

	Rhetoric **I.2**	***Prior Analytics*** **II.27**
(i)	Wise men are just, since Socrates is just.	Wise men are good, since Pittacus is good.
(ii)	He is ill, since he has fever.	This man has fever, since he breathes rapidly.
(iii)	She has given birth, since she has milk.	This woman has a child, since she has milk.
		She is pregnant, since she is pale.

Sign-arguments of type (i) and (iii) can always be refuted, even if the premises are true; that is to say that they do not include a valid deduction (*sullogismos*); Aristotle calls them *asullogistos* (non-deductive). Sign-arguments of type (ii) can never be refuted if the premise is true, since, for example, it is not possible that someone has fever without being ill, or that someone has milk without having given birth, etc. This latter type of sign-enthymemes is necessary and is also called *tekmêrion* (proof, evidence). Now, if some sign-enthymemes are valid deductions and some are not, it is tempting to ask whether Aristotle regarded the non-necessary sign-enthymemes as apparent or fallacious arguments. However, there seems to be a more attractive reading: We accept a fallacious argument only if we are deceived about its logical form. But we could regard, for example, the inference “She is pregnant, since she is pale.” as a good and informative argument, even if we know that it does not include a logically necessary inference. So it seems as if Aristotle didn't regard all non-necessary sign-arguments as fallacious or deceptive; but even if this is true, it is difficult for Aristotle to determine the sense in which non-necessary sign-enthymemes are valid arguments, since he is bound to the alternative of deduction and induction, and neither class seems appropriate for non-necessary sign-arguments.

7. The *Topoi*

Generally speaking, an Aristotelian *topos* ('place', 'location') is an argumentative scheme which enables a dialectician or rhetorician to construe an argument for a given conclusion. The use of so-called *topoi* or '*loci communes*' can be traced back to early rhetoricians such as Protagoras, Gorgias (cp. Cicero, *Brutus* 46-48) and Isocrates. But, while in earlier rhetoric a *topos* was understood as a complete pattern or formula that can be mentioned at a certain stage of the speech to produce a certain effect, most of the Aristotelian *topoi* are general instructions saying that a conclusion of a certain form can be derived from premises of a certain form; and because of this 'formal' or 'semi-formal' character of Aristotelian *topoi*, one *topos* can be used to construe several different arguments. —Aristotle's book *Topics* lists some hundred *topoi* for the construction of dialectical arguments. These lists of *topoi* form the core of the method by which the dialectician should be able to formulate deductions on any problem that could be proposed. Most of the instructions that the *Rhetoric* gives for the composition of enthymemes are also organized as lists of *topoi*; especially the first book of the *Rhetoric* essentially consists of *topoi* concerning the subjects of the three species of public speech.

7.1 The Definition of 'Topos'

It is striking that the work which is almost exclusively dedicated to the collection of *topoi*, the book *Topics*, does not even make an attempt to define the concept of *topos*. At any rate the *Rhetoric* gives a sort of defining characterization: "I call the same thing element and *topos*; for an element or a *topos* is a heading under which many enthymemes fall" (*Rhet.* 1403a18-19). By 'element' Aristotle does not mean a proper part of the enthymeme, but a general form under which many concrete enthymemes of the same type can be subsumed. According to this definition the *topos* is a general argumentative form or pattern, and the concrete arguments are instantiations of the general *topos*. That the *topos* is a general instruction from which several arguments can be derived, is crucial for Aristotle's understanding of an artful method of argumentation; for a teacher of rhetoric who makes his pupils learn ready samples of arguments would not impart the art itself to them, but only the products of this art, just as if someone pretending to teach the art of shoe-making only gave samples of already made shoes to his pupils (see *Sophistical Refutations* 183b36ff.).

7.2 The Word '*Topos*' and the Technique of Places

The word '*topos*' (place, location) most probably is derived from an ancient method of memorizing a great number of items on a list by associating them with successive places, say the houses along a street one is acquainted with. By recalling the houses along the street we can also remember the associated items. Full descriptions of this technique can be found in Cicero, *De Oratore* II 86-88, 351--360, *Auctor ad Herennium* III 16-24, 29-40, and in Quintilian, *Institutio* XI 2, 11-33). In *Topics* 163b28--32 Aristotle seems to allude to this technique: "For just as in the art of remembering, the mere mention of the places instantly makes us recall the things, so these will make us more apt at deductions through looking to these defined premises in order of enumeration." Aristotle also alludes to this technique in *On the soul* 427b18-

20, *On Memory* 452a12-16, and *On Dreams* 458b20-22.

But though the name ‘*topos*’ may be derived from this mnemotechnical context, Aristotle's use of *topoi* does not rely on the technique of places. At least within the system of the book *Topics*, every given problem must be analyzed in terms of some formal criteria: Does the predicate of the sentence in question ascribe a genus or a definition or peculiar or accidental properties to the subject? Does the sentence express a sort of opposition, either contradiction or contrariety etc.? Does the sentence express that something is more or less the case? Does it maintain identity or diversity? Are the words used linguistically derived from words that are part of an accepted premise? Depending such formal criteria of the analyzed sentence one has to refer to a fitting *topos*. For this reason the succession of *topoi* in the book *Topics* is organized in accordance with their salient formal criteria; and this, again, makes a further mnemotechnique superfluous. More or less the same is true of the *Rhetoric*—except that most of its *topoi* are structured by material and not by formal criteria as we shall see in section 7.4.—Besides all this, there is at least one passage in which the use of the word ‘*topos*’ can be explained without referring to the previously mentioned mnemotechnique: In *Topics* VIII.1, 155b4-5 Aristotle says: “we must find the location (*topos*) from which to attack,” where the word ‘*topos*’ is obviously used to mean a starting point for attacking the theses of the opponents.

7.3 The Elements of a *Topos*

A typical Aristotelian *topos* runs as follows: “Again, if the accident of a thing has a contrary, see whether it belongs to the subject to which the accident in question has been declared to belong: for if the latter belongs, the former could not belong; for it is impossible that contrary predicates should belong at the same time to the same thing.” (*Topics* 113a20-24). As most *topoi* it includes (i) a sort of general instruction (“see, whether …”); further it mentions (ii) an argumentative scheme—in the given example the scheme ‘if the accidental predicate *p* belongs to the subject *s*, then the opposed *P** cannot belong to *s* too’. Finally, the *topos* refers to (iii) a general rule or principle (“for it is impossible, …”) which justifies the given scheme. Other *topoi* often include the discussion of (iv) examples; still other *topoi* suggest (v) how to apply the given schemes.—Though these are elements that regularly occur in Aristotelian *topoi*, there is nothing like a standard form with which all *topoi* comply. Often Aristotle is very brief and leaves it to the reader to add the missing elements.

7.4 The Function of a *Topos*

In a nutshell, the function of a *topos* can be explained as follows. First of all one has to select an apt *topos* for a given conclusion. The conclusion is either a thesis of our opponent which we want to refute, or our own assertion we want to establish or defend. Accordingly, there are two uses of *topoi*: they can either prove or disprove a given sentence; some can be used for both purposes, others for only one of them. Most *topoi* are selected by certain formal features of the given conclusion; if, for example, the conclusion maintains a definition, we have to select our *topos* from a list of *topoi* pertaining to definitions, etc. When it comes to the so-called ‘material’ *topoi* of the *Rhetoric* the appropriate *topos* must be selected not by formal criteria, but in accordance with the content of the conclusion—whether, for example, something is

said to be useful or honorable or just, etc. Once we have selected a *topos* which is appropriate for a given conclusion, the *topos* can be used to construe a premise from which the given conclusion can be derived. If for example the argumentative scheme is 'If a predicate is generally true of a genus, then the predicate is also true of any species of that genus', we can derive the conclusion 'the capacity of nutrition belongs to plants' using the premise 'the capacity of nutrition belongs to all living things', since 'living thing' is the genus of the species 'plants'. If the construed premise is accepted, either by the opponent in a dialectical debate or by the audience in public speech, we can draw the intended conclusion.

It has been disputed whether the *topos* (or, more precisely, the 'if …, then …' scheme that is included in a *topos*) which we use to construe an argument must itself be regarded as a further premise of the argument. It could be a premise either, as some say, as the premise of a propositional scheme such as the modus ponens, or, as others assume, as the conditional premise of a hypothetical syllogism. Aristotle himself does not favor one of these interpretations explicitly. But even if he regarded the *topoi* as additional premises in a dialectical or rhetorical argument, it is beyond any doubt that he did not use them as premises which must explicitly be mentioned or even approved by the opponent or audience.

8.1 The Virtue of Style

[Not yet available]

8.2 Aristotelian Metaphors

According to Aristotle *Poetics* 21, 1457b9-16 and 20-22 a metaphor is "the application of an alien name by transference either from genus to species, or from species to genus, or from species to species, or by analogy, that is, proportion." These four types are exemplified as follows:

	Type	Example	Explanation
(i)	From genus to species	There lies my ship	Lying at anchor is a species of the genus "lying"
(ii)	From species to genus	Verily ten thousand noble deeds hath Odysseus wrought	Ten thousand is a species of the genus "large number"
(iii)	From species to species.	(a) With blade of bronze drew away the life	(a) "To draw away" is used for "to cleave"

	(b) Cleft the water with the vessel of unyielding bronze	(b) "To cleave" is used for "to draw away." Both, to draw away and to cleave, are species of "taking away"
(iv) From analogy.	(a) To call the cup "the shield of Dionysus"	(a) The cup is to Dionysus as the shield to Ares
	(b) To call the shield "the cup of Ares"	(b) The shield is to Ares as the cup to Dionysus

Most of the examples Aristotle offers for types (i) to (iii) would not be regarded as metaphors in the modern sense; rather they would fall under the headings of metonomy or synecdoche. The examples offered for type (iv) are more like modern metaphors. Aristotle himself regards the metaphors of group (iv), which are built from analogy, as the most important type of enthymemes. An analogy is given if the second term is to the first as the fourth to the third. Correspondingly, an analogous metaphor use the fourth term for the second, or the second for the fourth. This principle can be illustrated by the following Aristotelian examples:

	Analogy	Metaphor
(a)	The cup to Dionysus as shield to Ares.	To call the cup "the shield of Dionysus" or the shield "the cup of Ares" is a metaphor.
(b)	The old age to life as the evening to day	To call the old age "evening of the life" or the evening "old age of the day" is a metaphor
(c)	Sowing to seed as *X* to sun rays, while the action of the sun in scattering his rays is nameless; still this process bears to the sun the same relation as sowing to the seed.	To call (a nameless) *X* "sowing of sun rays" is a metaphor by analogy
(d)	= (a)	To call the shield "a cup without wine" is also a metaphor by analogy.

Examples (a) and (b) obey to the optional instruction that metaphors can be qualified by adding the term to which the proper word is relative (cp. "the shield *of Ares*," "the evening *of life*"). In example (c) there is no proper name for the thing which is referred to by the metaphor. In example (d) the relation of analogy is not, as in the other cases, indicated by the domain to which an item is referred to, but by a certain negation (for example "without name"); the negations make clear that the term is not used in its usual sense.

Metaphors are closely related to similes; but as opposed to the later tradition, Aristotle does not define the metaphor as a abbreviated simile, but, the other way around, the simile as metaphor. The simile differs from the metaphor in the form of expression: while in the metaphor something is identified or substituted, the simile compares two things with each other, using words as "like," "as" etc. For example, "He rushed

as a lion," is, according to Aristotle, a simile, but "The lion rushed," is a metaphor.

While in the later tradition the use of metaphors has been seen as a matter of mere decoration, which has to delight the hearer, Aristotle stresses the cognitive function of metaphors. Metaphors, he says, bring about learning (*Rhet.* III.10, 1410b14f.). In order to understand a metaphor, the hearer has to find something common between the metaphor and the thing which the metaphor is referred to. For example, if someone calls the old age "stubble," we have to find a common genus to which old age and stubble belong; we do not grasp the very sense of the metaphor until we find that both, old age and stubble, have lost their bloom. Thus, a metaphor does not only refer to a thing, but simultaneously describes the respective thing in a certain respect. This is why Aristotle says that the metaphor brings about learning: as soon as we understand why someone uses the metaphor "stubble" to refer to old age, we have learned at least one characteristic of old age.

Glossary of Selected Terms

- Accepted opinions: *endoxa*
- Argument: *logos*
- Art: *technê*
- Character: *êthos*
- Counterpart: *antistrophos*
- Credible: *axiopistos*
- Decision (practical): *prohairesis*
- Deduction: *sullogismos*
- Emotions: *pathê*
- Enthymeme: *enthumêma*
- Example: *paradeigma*
- For the most part: *hôs epi to polu*
- Induction (*epagôgê*)
- Judgement: *krisis*
- Location: *topos* (an argumentative scheme)
- Maxim: *gnômê*
- Means of persuasion: *pistis* (in pre-Aristotelian use this word also designates a certain part of the speech)
- Metaphor: *metaphora*
- Persuasive: *pithanon*
- Place: *topos* (an argumentative scheme)
- Practical intelligence: *phronêsis*
- Premise: *protasis* (can also mean 'sentence', statement')
- Probable: *eikos*
- Proof: *apodeixis* (in the sense of 'demonstrative argument, demonstration')
- Proof: *tekmêrion* (i.e. a necessary sign or sign argument)
- Sign: *sêmeion* (can also mean 'sign argument')

- Style: *lexis*
- Specific *topoi*: *idioi topoi* (Aristotle refers to them also by '*idiai protaseis*' or '*eidê*')

Supplement to Aristotle's Rhetoric

The Brevity of the Enthymeme

In Rhet. II.22, 1395b24-26, a passage which is parallel to Rhet. I.2, 1357a7-18, Aristotle says that the orator should avoid two tendencies: in formulating enthymemes one should neither (a) deduce from far away nor (b) take up everything. Traditionally, this description has been associated with the alleged logical incompleteness of the enthymeme. But again one cannot infer that the enthymeme has to leave out logically required premises: (a) Deducing from too far away means that the orator has chosen premises that are so remote that it is difficult to see the connection with the intended conclusion (for example, if the premise is a rather general principle and the conclusion pertains to a concrete decision). But this is a question which does not even affect the number or completeness of the used premises (it affects the length of the argument only if one tries to bridge the span between the original premise and the conclusion by several intermediate steps). Whether or not one (b) takes up everything, can, but must not affect the logical completeness of an argument: Let us assume that someone has chosen a very remote premise as in the argument that the Scythians have no flute players, since they have no wine plants. Obviously, the respective arguments can be construed in different ways. On the one hand one could put it in the straight form:

> (P_1): Since there is no wine in the land of the Scythians and
> (P_2): since flute-players can only be found where there is wine,
> (C): the Scythians have no flute-players.

But most probably this argument would not be persuasive, since the premise (P_2) can hardly be taken as a generally accepted and evident opinion. On the other hand one could take up everything to elucidate the connection to the intended conclusion; for example: “Since the art of flute-playing only flourishes where there are glittering parties, and glittering parties can only be where the guests get drunk, and the guests only get drunk where there is a sufficient supply of wine, and a sufficient supply of wine is only where … etc.” This latter method takes up everything, even things that are already evident. This is exactly what the orator has to avoid. But either way, whether one takes up everything or not, the argument can be a complete deduction. Therefore, the advice that enthymemes should be short and should not have redundant premises can, but need not affect the logical completeness of an argument. The fallacious tendencies of deducing from far away and taking up everything can be avoided if one starts with apt premises.

Supplement to Aristotle's Rhetoric

The *topoi* of the Rhetoric

Interpreters are faced with the problem that the use of the word ‘*topos*’ in Aristotle’s *Rhetoric* is much more heterogeneous than in the *Topics*. Beside *topoi* which do perfectly comply with the description given in the *Topics*, there is an important group of *topoi* in the *Rhetoric* which contain instructions for arguments not of a certain form, but with a certain predicate (for example, that something is good, or honorable, or just, or contributes to happiness etc.). While those material *topoi* are still used to build arguments, there are also uses of ‘*topos*’ in the context of the non-argumentative means of persuasion.

In I.2, 1358a2-35 Aristotle distinguishes between general/common *topoi* on the one hand and specific *topoi* on the other hand. In chapter I.2 he explains the sense of ‘specific’ by pointing out that some things are specific to physics, others to ethics, etc. But from chapter I.3 on he makes us think that ‘specific’ refers to the different species of rhetoric, so that some *topoi* are specific to deliberative, other to epideictic, and still others to juridical speech. While he is inclined to call the general or common *topoi* simply ‘*topoi*’, he uses several names for the specific *topoi* (*idiai protaseis*, *eidê*, *idioi topoi*). Roughly, it is clear that the specific *topoi* can be found in the first and the common *topoi* in the second book of the *Rhetoric*. Most interpreters assumed that all common *topoi* are listed in chapters II.23-24 (for real enthymemes in II.23, for fallacious enthymemes in II.24), but failed to notice that more common *topoi* can be found in II.19. Further, it may be tempting to call, as some do, the specific *topoi* ‘material’ and the common *topoi* ‘formal’; but in so doing interpreters often neglected that some of the common *topoi* in chapters II.23-24 are not all based on those formal categories on which the *topoi* of the *Topics* rely. Most of them are ‘common’ only in the sense that they are not specific to one single species of speech. Some of them only offer strategic advice, as, for example, to turn what has been said against oneself upon the one who said it. For this reason, it is completely misleading to say that the functions of specific and common *topoi* are complementary, insofar as the common *topoi* allegedly offer the logical form to a content that has been provided by the specific ones.

The specific *topoi* of the Rhetoric

Since Aristotle sometimes calls the specific *topoi* ‘*protaseis*’, and ‘*protasis*’ is at the same time the Greek word for ‘premise’ and ‘statement, sentence’, his treatment of specific *topoi* gave rise to serious confusions. Several authors subscribed to the view of Friedrich Solmsen that there are two types of enthymemes, insofar as some are taken from *topoi* and some are built from premises, not from *topoi*. According to this view the specific *topoi* given in the first book of the *Rhetoric* are the premises of the latter type of enthymemes ,and the enthymemes of the former type are taken only from common *topoi*. From this point of view only common *topoi* would be *topoi* in the proper sense, while specific *topoi*

would be, strictly speaking, nothing else but premises. Accordingly, one would expect to find sentences of the form “All *F* are just/noble/good” in the first book of the *Rhetoric*; with such sentences one could construe syllogisms like “All *F* are just/noble/good—This particular *x* is *F*—This particular *x* is just/noble/good.” But what we actually find in the first book hardly fits Solmsen’s model. In some sense we find more than the required premises, insofar as Aristotle not only gives us isolated sentences, but also certain sentences together with a reason or a justification. Further Solmsen can hardly make sense of the fact that Aristotle calls these alleged premises ‘*topoi*’. And above all, chapters I.6-7 of the *Rhetoric* offer *topoi* which can also be found in the third book of *Topics*; in the *Topics* they are clearly called ‘*topoi*’, so that there is no reason to assume that they are premises rather than *topoi*.

The general idea by which the specific *topoi* can be characterized is rather this: Every specific *topos* gives us a general (but not formal) description of things that are supposed to be good, noble, just etc. It also gives us a reason with which we are enabled to argue that the things described are good, noble, just etc. Typically, this reason refers the given description back to a generally held definition of what is good, noble, just etc., which is provided at the outset the several chapters. In some cases the reason is directly, in some cases it is indirectly linked with the initial definition. Example: The specific *topos* is: “what is pleasant is good, since it is desirable.” The phrase “what is pleasant” provides the general description, the phrase “since it is desirable” provides the reason. Now, at the beginning of the chapter the good has been defined as “what is desirable.” Another specific *topos* is “honor is good, since it is pleasant”; here the reason in question applies the previous *topos* that what is pleasant is good, so that the current *topos* is indirectly linked with the initial definition of what is good. The general description included in those *topoi* enables us to identify cases which the orator can present as good, noble, just etc., the added reason shows us how to argue for the goodness etc. of the selected things. Thus, the specific *topoi* do not only provide premises but complete argumentative patterns.

Several types of rhetorical topoi

The several topoi that can be found under the headings ‘specific’ and ‘common’ do not at all make up two homogeneous classes. Some of them have only a vague affinity to the standard form of topoi which prevails in the book *Topics*. Some so-called topoi of the Rhetoric neither belong to the specific nor to the common class, but are just instructions or patterns which are somehow useful in public speech. At least the following groups must be distinguished:

	Place	Description	Examples
(i)	I.5-14 (without I.6b—I.7)	specific *topoi* of the three species of speech	“Further, health, beauty, and the like are goods, for being bodily excellences and productive of many other good things.” “It is noble to avenge oneself on one's enemies and not to come to terms with them; for requital is just, and the just is noble.”

(ii)	I.6b	*topoi* on controversial goods	"That which most people seek after, and which is obviously an object of contention, is also a good; for, as has been shown, that is good which is sought after by everybody, and 'most people' is taken to be equivalent to 'everybody'."
(iii)	I.7	*topoi* on the greater good (the better)	"Again, where one good is always accompanied by another, but does not always accompany it, it is greater than the other, for the use of the second thing is implied in the use of the first."
(iv)	I.15	*topoi* of non-technical means of persuasion	"We shall argue that justice indeed is true and profitable, but that sham justice is not, and that consequently the written law is not, because it does not fulfill the true purpose of law."
(v)	II.2-11, II.12-17	*topoi* to arouse emotions	"Again we are angry if something is not in line with what we expected, since what is not in line with what we expect provides more pain."
(vi)	II.19	*topoi* about the possible, the past, the future	"If the beginning of a thing can occur, so can the end; for nothing impossible occurs or begins to occur."
(vii)	II.23-24	common *topoi* (type 1)	"If a quality does not in fact exist where it is more likely to exist, it clearly does not exist where it is less likely."
(viii)	II.23-24	common *topoi* (type 2)	"Another line of argument is common to forensic and deliberative oratory, namely, to consider inducements and deterrents, and the motives people have for doing or avoiding the actions in question."
(ix)	II.23-24	common *topoi* (type 3)	"Another line is to apply to the other speaker what he has said against yourself."

(x)	III.15	topoi for slandering	"Another method is to denounce calumny, by saying what an enormity it is, and in particular that it raises false issues, and that it means a lack of confidence in the merits of his case."

Typical examples of group (i) can be found in chapters I.5-6 (first half), 9 and others. Starting form a definition of what is happiness, good, honorableand just etc., those *topoi* instruct arguments to the effect that items of a certain type are part of happiness, are good, honorable, just etc. The groups (ii) und (iii) have been inserted to indicate that the so-called specific *topoi* include various kinds of instructions: while the *topoi* of the first group offer determinate premises from which one can deduce that items of a certain type are good, just etc., the *topoi* of groups (ii) to (iii) help to construe diverse premises for items of several kinds. The *topoi* of group (iv) tell the orator what to say if one is using non-technical (i.e. artless) means of persuasion such as contracts, laws, witnesses etc. Just as the *topoi* of group (x), which offers the orators formulas for slandering, the underlying concept of *topos* in this group is essentially the same as in the pre-Aristotelian usage. The items mentioned in group (v) by which the orator should be enabled to arouse certain emotions in different contexts are also called '*topoi*', though they do not contribute to argumentation in the strictest sense. With respect to their formal character the topoi of group (vi) are quite familiar to the topoi of the *Topics*. The topoi of groups (vii) to (ix) are common insofar as they are not connected with a certain species of rhetoric. But while the topoi of group (vii) are roughly of the same type as the topoi of the *Topics*, other so-called 'common' topoi are exclusively suited for rhetorical purposes; the *topoi* of group (ix) only offer strategic advices.

Georg Wilhelm Friedrich Hegel

Along with J. G. Fichte and F. W. J. von Schelling, Hegel (1770-1831) belongs to the period of “German idealism” in the decades following Kant. The most systematic of the post-Kantian idealists, Hegel attempted, throughout his published writings as well as in his lectures, to elaborate a comprehensive and systematic ontology from a “logical” starting point. He is perhaps most well-known for his teleological account of history, an account which was later taken over by Marx and “inverted” into a materialist theory of an historical development culminating in communism. For most of the twentieth century, the “logical” side of Hegel's thought had been largely forgotten, but his political and social philosophy continued to find interest and support. However, since the 1970s, a degree of more general philosophical interest in Hegel's systematic thought has also been revived.

1. Life, Work, and Influence

Born in 1770 in Stuttgart, Hegel spent the years 1788-1793 as a theology student in nearby Tübingen, forming friendships there with fellow students, the future great romantic poet Friedrich Hölderlin (1770-1843) and Friedrich W. J. von Schelling (1775-1854), who, like Hegel, would become one of the major figures of the German philosophical scene in the first half of the nineteenth century. These friendships clearly had a major influence on Hegel's philosophical development, and for a while the intellectual lives of the three were closely intertwined.

After graduation Hegel worked as a tutor for families in Bern and then Frankfurt, where he was reunited with Hölderlin. Until around 1800, Hegel devoted himself to developing his ideas on religious and social themes, and seemed to have envisaged a future for himself as a type of modernising and reforming educator, in the image of figures of the German Enlightenment such as Lessing and Schiller. Around the turn of the century, however, possibly under the influence of Hölderlin, his interests turned more to the issues in the "critical" philosophy of Immanuel Kant (1724-1804) that had enthused Hölderlin, Schelling, and many others, and in 1801 he moved to the University of Jena to join Schelling. In the 1790s Jena had become a centre of both "Kantian" philosophy and the early romantic movement and by the time of Hegel's arrival Schelling had already become an established figure, taking the approach of J. G. Fichte (1762-1814), the most important of the new Kantian-styled philosophers, in novel directions. In late 1801, Hegel published his first philosophical work, *The Difference between Fichte's and Schelling's System of Philosophy*, and up until 1803 worked closely with Schelling, with whom he edited the *Critical Journal of Philosophy*. In his "*Difference*" essay Hegel had argued that Schelling's approach succeeded where Fichte's failed in the project of systematising and thereby completing Kant's transcendental idealism, and on the basis of this type of advocacy was dogged for many years by the reputation of being a "mere" follower of Schelling (who was five years his junior).

By late 1806 Hegel had completed his first major work, the *Phenomenology of Spirit* (published 1807), which showed a divergence from his earlier, seemingly more Schellingian, approach. Schelling, who had left Jena in 1803, interpreted a barbed criticism in the *Phenomenology*'s preface as aimed at him, and their friendship abruptly ended. The occupation of Jena by Napoleon's troops as Hegel was completing the manuscript closed the university and Hegel left the town. Now without a university appointment he worked for a short time, apparently very successfully, as an editor of a newspaper in Bamberg, and then from 1808-1815 as the headmaster and philosophy teacher at a "gymnasium" in Nuremberg. During his time at Nuremberg he married and started a family, and wrote and published his *Science of Logic*. In 1816 he managed to return to his university career by being appointed to a chair in philosophy at the University of Heidelberg. Then in 1818, he was offered and took up the chair of philosophy at the University of Berlin, the most prestigious position in the German philosophical world. While in Heidelberg he published the *Encyclopaedia of the Philosophical Sciences*, a systematic work in which an abbreviated version of the earlier *Science of Logic* (the "Encyclopaedia Logic" or "Lesser Logic") was followed by the application of its principles to the *Philosophy of Nature* and the *Philosophy of Spirit*. In 1821 in Berlin Hegel published his major work in political philosophy, *Elements of the Philosophy of Right*, based on lectures given at Heidelberg but ultimately grounded in the section of the Encyclopaedia *Philosophy of Spirit* dealing with "objective spirit." During the following ten years up to his death in 1831 Hegel enjoyed celebrity at Berlin, and published subsequent versions of the *Encyclopaedia*. After his death versions of his lectures on philosophy of history, philosophy of religion, aesthetics, and the history of philosophy were published.

After Hegel's death, Schelling, whose reputation had long since been eclipsed by that of Hegel, was invited to take up the chair at Berlin, reputedly because the government of the day had wanted to counter the influence that Hegelian philosophy had developed among a generation of students. Since the early period of his collaboration with Hegel, Schelling had become more religious in his philosophising and

criticised the “rationalism” of Hegel's philosophy. During this time of Schelling's tenure at Berlin, important forms of later critical reaction to Hegelian philosophy developed. Hegel himself had been a supporter of progressive but non-revolutionary politics, but his followers divided into “left-” and “right-wing” factions; from out of the former circle, Karl Marx was to develop his own “scientific” approach to society and history which appropriated many Hegelian ideas into Marx's materialistic outlook. (Later, especially in reaction to orthodox Soviet versions of Marxism, many “Western Marxists” re-incorporated further Hegelian elements back into their forms of Marxist philosophy.) Many of Schelling's own criticisms of Hegel's rationalism found their way into subsequent “existentialist” thought, especially via the writings of Kierkegaard, who had attended Schelling's lectures. Furthermore, the interpretation Schelling offered of Hegel during these years itself helped to shape subsequent generations' understanding of Hegel, contributing to the orthodox or traditional understanding of Hegel as a “metaphysical” thinker in the pre-Kantian “dogmatic” sense.

In academic philosophy, Hegelian idealism underwent a revival in both Great Britain and the United States in the last decades of the nineteenth century. In Britain, where philosophers such as T. H Green and F. H. Bradley had developed metaphysical ideas which they related back to Hegel's thought, Hegel came to be one of the main targets of attack by the founders of the emerging “analytic” movement, Bertrand Russell and G. E. Moore. For most of the twentieth century, interest in Hegel became limited to the context of his relation to other more popular philosophical movements like existentialism or Marxism, or to his social and political thought. In France, a version of Hegelianism came to influence a generation of thinkers, including Jean-Paul Sartre and the psychoanalyst, Jacques Lacan, largely through the lectures of Alexandre Kojève, an important precursor to the later “post-modern” movement. A later generation of French philosophers coming to prominence in the late 1960s and after, however, tended to react against Hegel in ways analogous to those in which early analytic philosophers had reacted against the Hegel who had influenced their predecessors. In Germany, interest in Hegel was revived early in the century with the historical work of Wilhelm Dilthey, and important Hegelian elements were incorporated into the approach of thinkers of the Frankfurt School, such as Theodor Adorno, and later, Jürgen Habermas, as well as the “hermeneutic” approach of H.-G. Gadamer. In Hungary, similar Hegelian themes were developed by Georg Lukács and later thinkers of the “Budapest School.” In the 1960s the German philosopher Klaus Hartmann developed what was termed a “non-metaphysical” interpretation of Hegel which, together with the work of Dieter Henrich and others, played an important role in the revival of interest in Hegel in academic philosophy in the second half of the century. Within English-speaking philosophy, the final quarter of the twentieth century saw something of a revival of serious interest in Hegel's philosophy, especially in North America, with important works appearing such as those by H. S. Harris, Charles Taylor, Robert Pippin and Terry Pinkard.

2. Hegel's Philosophy

Hegel's own pithy account of the nature of philosophy given in the “Preface” to his *Elements of the Philosophy of Right* captures a characteristic tension in his philosophical approach and, in particular, in his approach to the nature and limits of human cognition. “Philosophy,” he says there, “is its own time raised to the level of thought.”

On the one hand we can clearly see in the phrase “its own time” the suggestion of an historical or cultural conditionedness and variability which applies even to the highest form of human cognition, philosophy itself -- the contents of philosophical knowledge, we might suspect, will come from the historically changing contents of contemporary culture. On the other, there is the hint of such contents being “raised” to some higher level, presumably higher than other levels of cognitive functioning -- those based in everyday perceptual experience, for example, or those characteristic of other areas of culture such as art and religion. This higher level takes the form of “thought” -- a type of cognition commonly taken as capable of having “eternal” contents (think of Plato and Frege, for example).

This antithetical combination within human cognition of the temporally-conditioned and the eternal, a combination which reflects a broader conception of the human being as what Hegel describes elsewhere as a “finite-infinite,” has led to Hegel being regarded in different ways by different types of philosophical readers. For example, an historically-minded pragmatist like Richard Rorty, distrustful of all claims or aspirations to the “God's-eye view,” could praise Hegel as a philosopher who had introduced this historically reflective dimension into philosophy (and setting it on the characteristically “hermeneutic” path which has predominated in modern continental philosophy) but who had unfortunately still remained bogged down in the remnants of the Platonistic idea of the search for ahistorical truths. Those adopting such an approach to Hegel tend to have in mind the (relatively) young author of the *Phenomenology of Spirit* and have tended to dismiss as “metaphysical” later and more systematic works like the *Science of Logic*. In contrast, the British Hegelian movement at the end of the nineteenth century, for example, tended to ignore the *Phenomenology* and the more historicist dimensions of his thought, and found in Hegel a systematic metaphysician whose *Logic* provided a systematic and definitive philosophical ontology of an idealist type. This latter traditional, “metaphysical” view of Hegel dominated Hegel reception for most of the twentieth century, but has over the last few decades been contested by many Hegel scholars who have offered an alternative, “post-Kantian” view of Hegel.

2.1 The traditional “metaphysical” view of Hegel's philosophy

Given the understanding of Hegel that predominated at the time of the birth of analytic philosophy together with the fact that early analytic philosophers were rebelling precisely against “Hegelianism” so understood, the “Hegel” encountered in discussions within analytic philosophy is often that of the late nineteenth-century interpretation. In this picture, Hegel is seen as offering a metaphysico-religious view of “Absolute Spirit” which draws on pantheistic ideas of the identity of the universe and God, together with theistic ideas concerning the necessary “self-consciousness” of God. The peculiarity of Hegel's view, on this account, lies in his idea that the mind of God becomes actual only via the minds of his creatures, who serve as its vehicle. It is as distributed bearers of this developing self-consciousness of God that those finitely-embodied inhabitants of the universe -- we humans -- can be such “finite-infinites.”

An important consequence of Hegel's metaphysics, so understood, concerns history and the idea of historical development or progress, and it is as an advocate of an idea concerning the logically-necessitated teleological course of history that Hegel is most often decried. To many critics Hegel not

only was an advocate of a disastrous political conception of the state and the relation of its citizens to it, a conception prefiguring twentieth-century totalitarianism, but had tried to underpin such advocacy with dubious logico-metaphysical speculations. With his idea of the development of “spirit” in history, Hegel is seen as literalising a way of talking about different cultures in terms of their “spirits,” of constructing a developmental sequence of epochs typical of nineteenth-century ideas of linear historical progress, and then enveloping this story of human progress in terms of one about the developing self-conscious of the cosmos-God itself.

As the bottom line of such an account concerned the evolution of states of a mind (God's), such an account is clearly an idealist one, but not in the sense, say, of Berkeley. The pantheistic legacy inherited by Hegel meant that he had no problem in considering an objective *outer* world beyond any particular subjective mind. But this objective world itself had to be understood as conceptually informed, as it were -- it was *objectified* spirit. Thus in contrast to Berkeleian “subjective idealism” it became common to talk of Hegel as incorporating the “objective idealism” of views, especially common among German historians, in which social life and thought were understood in terms of the conceptual or “spiritual” structures that informed them. But in contrast to both forms of idealism, Hegel, according to this reading, postulated a form of *absolute* idealism by including both subjective life and the objective cultural practices on which subjective life depended within the dynamics of the development of the self-consciousness and self-actualisation of God, the “Absolute Spirit.”

It is hardly surprising, given the more secular character of much twentieth-century philosophy, that Hegel, so understood, would be generally regarded as of merely historical interest. Nevertheless, Hegel was still seen by many as an important precursor of other more characteristically modern strands of thought such as existentialism and Marxist materialism. Existentialists were thought of as taking the idea of the finitude and historical and cultural dependence of individual subjects from Hegel and leaving out all pretensions to the “absolute,” while Marxists were thought of as taking the historical dynamics of the Hegelian picture but understanding this in materialist rather than idealist categories. But while the traditional view of Hegel remained a commonplace throughout the twentieth century it has come to be increasingly questioned as an accurate account of Hegel's philosophy within Hegel scholarship itself. In the last quarter of the century, an increasing number of Hegel interpreters argued that such an understanding was seriously flawed, and while various quite different philosophical interpretations of Hegel have emerged which attempt to acquit him of implausible metaphysico-theological views, one common tendency has been to stress the continuity of his ideas with the “critical philosophy” of Immanuel Kant.

2.2 The non-traditional or “post-Kantian” view of Hegel

Least controversially, it has been claimed that either particular works such as the *Phenomenology of Spirit*, or particular areas of Hegel's philosophy, especially his ethical and political philosophy, can be understood as standing independently of the type of unacceptable metaphysical system sketched above. Somewhat more controversially, it has also been argued that the traditional picture is simply wrong at a more general “metaphysical” level and that Hegel is in no way committed to the bizarre “spirit monism”

that has been traditionally attributed to him. While these latter views often differ among themselves and continue to take exception to various aspects of Hegel's actual work, they commonly agree in regarding Hegel as being a “post-Kantian” philosopher who had accepted that aspect of Kant's critical philosophy which has been the most influential, his critique of traditional “dogmatic” metaphysics. Thus while the traditional view sees Hegel as exemplifying the very type of metaphysical speculation that Kant successfully criticised, the post-Kantian view of Hegel sees him as both accepting and extending Kant's critique, even of turning it against the residual “dogmatically metaphysical” aspects of Kant's own philosophy.

To see Hegel as a post-Kantian is to regard him as extending that “critical” turn that Kant saw as setting his philosophy on a scientific footing in a way analogous to the work of Copernicus in cosmology. With his Copernican analogy Kant had compared the way that the positions of the sun and earth were reversed in Copernicus' transformation of cosmology to the way that the positions of knowing subject and known object were reversed in his own transcendental idealism. Objectivity could no longer be thought as a matter of mental representations “corresponding” to an object “in itself” . Having posed the question of the ground of the relation of a representation to an object, Kant had answered that where a representation was not made possible by the process of sensory affection, it could be justified as objective only if through it it became possible to *cognise* something *as an object*.

No sooner had Kant's philosophy appeared then many objections were raised, among which were complaints about the apparently irreducible gap between the mind qua universal discursive intelligence and the mind as individual psychological reality. Kantian ideas were quickly integrated by Schelling with extant Spinozist ideas concerning mind and body as different aspects of an underlying substance to yield a type of philosophical biology. Others, such as Wilhelm von Humboldt and Friedrich D. E. Schleiermacher joined Kantian ideas about the mind with philological ideas linking thought to the structures of historically variable languages. Other critics pointed to internal inconsistencies in Kant's picture in which the world in itself seemed to be thought of on the one hand as the cause of its appearance, and on the other, as beyond knowledge and its constituent categories such as “cause.” Among the ambitions of many of Kant's successors, including Hegel, was that of somehow “completing” Kant. In Hegel especially, many argue, one can see the ambition to bring together the universalist dimensions of Kant's transcendental program with the culturally particularist conceptions of his more historically and relativistically-minded contemporaries. This resulted in his controversial conception of “spirit,” as developed in his *Phenomenology of Spirit*. With this notion, it has been argued, Hegel was pursing the Kantian question of the conditions of rational human “mindedness” rather than being concerned with giving an account of the developing self-consciousness of God. But while Kant had limited such conditions to “formal” structures of the mind, Hegel extended them to include aspects of historically and socially determined forms of embodied existence.

3. Hegel's Works

3.1 Phenomenology of Spirit

The term “phenomenology” had been coined by the German scientist and mathematician (and Kant correspondent) J. H. Lambert (1728 -- 1777), and in a letter to Lambert, sent to accompany a copy of his “Inaugural Dissertation” (1770), Kant had proposed a “general phenomenology” as a necessary “propaedeutic” presupposed by the science of metaphysics. Such a phenomenology was meant to determine the “validity and limitations” of what he called the “principles of sensibility,” principles he had (he thought) shown in the accompanying work to be importantly different to those of conceptual thought. The term clearly suited Kant as he had distinguished the “phenomena” known through the faculty of sensibility from the “noumena” known conceptually. This envisioned “phenomenology” seems to coincide roughly with what he was to eventually entitle a “critique of pure reason,” although Kant's thought had gone through important changes by the time that he came to publish the work of that name (1781, second edition 1787). Perhaps because of this he never again used the term “phenomenology” for quite this purpose.

There is clearly some continuity between this Kantian notion and Hegel's project. In a sense Hegel's phenomenology is a study of “phenomena” (although this is not a realm he would contrast with that of “noumena”) and Hegel's *Phenomenology of Spirit* is likewise to be regarded as a type of “propaedeutic” to philosophy rather than an exercise in it -- a type of induction or education of the reader to the “standpoint” of purely conceptual thought of philosophy itself. As such, its structure has been compared to that of an “educational novel,” having an abstractly conceived protagonist -- the bearer of an evolving series of “shapes of consciousness” or the inhabitant of a series of successive phenomenal worlds -- whose progress and set-backs the reader follows and learns from. Or at least this is how the work sets out: in the later sections the earlier series of “shapes of consciousness” becomes replaced with what seem more like configurations of human social existence, and the work comes to look more like an account of interlinked forms of social existence and thought, the series of which maps onto the history of western European civilization from the Greeks to Hegel's own time. The fact that it ends in the attainment of “Absolute Knowing,” the standpoint from which real philosophy gets done, seems to support the traditionalist reading in which a “triumphalist” narrative of the growth of western civilization is combined with the theological interpretation of God's self-manifestation and self-comprehension. When Kant had broached the idea of a phenomenological propaedeutic to Lambert, he himself had still believed in the project of a purely conceptual metaphysics, but this was a project that in his later critical philosophy he came to disavow. Traditional readers of Hegel thus see the *Phenomenology*'s telos as attesting to Hegel's “pre-Kantian” (that is, “pre-critical”) outlook and his embrace of the metaphysical project that Kant famously came to dismiss as illusory. Supporters of the non-metaphysical Hegel obviously interpret this work and its telos differently. For example, some have argued that what this history tracks is the development of a type of social existence which enables a unique form of rationality, in that in such a society all dogmatic bases of thought have been gradually replaced by a system in which all claims become open to rational self-correction, by becoming exposed to demands for conceptually-articulated justifications.

Something of Hegel's phenomenological method may be conveyed by the first few chapters, which are perhaps among the more conventionally philosophical parts. Chapters 1 to 3 effectively follow a developmental series of “shapes of consciousness” or conscious attitudes which seem to be based upon distinct criteria for epistemic certainty. Chapter 1, “Sense-certainty” considers an epistemological attitude

involving an appeal to some immediately given perceptual contents -- the sort of role played by “sense data” in some early twentieth-century approaches to epistemology, for example. By following the protagonist's attempts to make these implicit criteria *explicit* we are meant to appreciate that any such contents, even the apparently most “immediate,” in fact contain implicit conceptually articulated presuppositions, and so, in Hegel's terminology, are “mediated.” One might compare Hegel's point here to that expressed by Kant in his well known claim that without concepts, those singular and immediate mental representations he calls “intuitions” are “blind.” In more recent terminology one might talk of the “concept-” or “theory-ladenness” of all experience, and the lessons of this chapter have been likened to that of Wilfrid Sellars's famous criticism of the “myth of the given.”

By the end of this chapter our protagonist consciousness (and by implication, we the audience to this drama) has learnt that the nature of consciousness cannot be as originally thought, rather its contents must have some implicit universal (conceptual) aspect to them. Consciousness thus now commences anew with its new implicit epistemic criterion -- the assumption that since the contents of consciousness are “universal” they must be publicly graspable by others as well. Hegel's name for this type of perceptual realism in which any individual's idiosyncratic private apprehension will always be in principle correctable by the experience of others is “perception” (*Wahrnehmung* -- in German this term having the connotations of *taking* (*nehmen*) to be *true* (*wahr*)). As with the case for “sense-certainty,” here again, by following the protagonist consciousness's efforts to make this implicit criterion explicit, we see how the criterion generates contradictions which eventually undermine it *as* a criterion for certainty. In fact, such collapse into a type of self-generated scepticism is typical of all the “shapes” we follow in the work, and there seems something inherently skeptical about such reflexive cognitive processes. But Hegel's point is equally that there has always been something *positive* that has been learned in such processes, and this learning is more than that which consists in the mere elimination of epistemological dead-ends. Rather, as in the way that the internal contradictions that emerged from sense-certainty had generated a new shape, perception, the collapse of any given attitude always involves the emergence of some new implicit criterion which will be the basis of a new emergent attitude. In the case of “perception,” the emergent new shape of consciousness Hegel calls “understanding” -- a shape which he identifies with scientific cognition rather than that of everyday “perception.”

The transition from Chapter 3 to 4, “The Truth of Self-Certainty,” also marks a more general transition from “consciousness” to “self-consciousness.” It is in the course of chapter 4 that we find what is perhaps the most well-known part of the *Phenomenology*, the account of the “struggle of recognition” in which Hegel examines the intersubjective conditions which he sees as necessary for any form of “consciousness“.

Like Kant, Hegel thinks that one's capacity to be “conscious” of some external object as something *distinct* from oneself requires the reflexivity of “self-consciousness,” that is, it requires one's awareness *of oneself* as a subject *for whom* something distinct, the object, is presented *as known*. Hegel goes beyond Kant, however, in making this requirement dependent on one's recognition (or acknowledgment -- *Anerkennung*) *as a subject* by *other* self-consciousnesses whom one recognises in turn. In short, one's *self*-consciousness is in no sense direct, as it was for Descartes, for example. It comes about only indirectly via one's recognising other conscious subjects' *recognition* of oneself! It is in this way that the

Phenomenology can change course, the earlier tracking of “shapes of consciousness” being effectively replaced by the tracking of distinct patterns of “mutual recognition” between subjects.

It is thus that Hegel has effected the transition from a phenomenology of “subjective mind,” as it were, to one of “objective spirit,” thought of as culturally distinct patterns of social interaction analysed in terms of the patterns of reciprocal recognition they embody. (“*Geist*” can be translated as either “mind” or “spirit,” but the latter, allowing a more cultural sense, as in the phrase “spirit of the age” (“*Zeitgeist*”), seems a more suitable rendering for the title.) But this is only worked out in the text gradually. We -- the reading, “phenomenological” we -- can see how particular shapes of self-consciousness, such as that of the other-worldly religious self-consciousness (“unhappy consciousness”) with which chapter 4 ends, depend on certain institutionalised forms of mutual recognition. But *we* are seeing this from the “outside” as it were, we still have to learn how real *in situ* self-consciousnesses could learn this of *themselves*. So we have to see how the protagonist self-consciousness could achieve this insight. It is to this end that we further trace the learning path of self-consciousness through the processes of “reason” (in chapter 5) before “objective spirit” can become the *explicit* subject matter of chapter 6, (*Spirit*).

Hegel's discussion of spirit starts from what he calls “*Sittlichkeit*” (translated as “ethical order” or “ethical substance”), “*Sittlichkeit*” being a nominalisation from the adjectival (or adverbial) form “*sittlich*,” “customary,” from the stem “*Sitte*” -- “custom” or “convention.” Thus Hegel might be seen as adopting the viewpoint that since social life is ordered by customs we can approach the lives of those living in it in terms of the patterns of those customs or conventions themselves -- the conventional practices, as it were, constituting specific *forms of life*. It is not surprising then that his account of spirit here starts with a discussion of religious and civic law. Undoubtedly it is Hegel's tendency to nominalise such abstract concepts as “customary” in his attempt to capture the *concrete* nature of such as patterns of conventional life, together with the tendency to then *personify* them (as in talking about “spirit” becoming “self-conscious”) that lends plausibility to the traditionalist understanding of Hegel. But for non-traditionalists it is not obvious that Hegel is in any way committed to any metaphysical supra-individual conscious beings with such usages. To take an example, in the second section of the chapter “Spirit” Hegel discusses “culture” as the “world of self-alienated spirit.” The idea seems to be that humans in society not only interact, but that they collectively create relatively enduring cultural products (stories, dramas, and so forth) within which they can recognise their own patterns of life reflected. We might find intelligible the idea that such products “hold up a mirror to society” within which “the society can regard itself,” without thinking we are thereby committed to some supra-individual social “mind” achieving self-consciousness. Furthermore, such cultural products themselves provide conditions allowing individuals to adopt particular cognitive attitudes. Thus, for example, the capacity to adopt the type of objective viewpoint demanded by Kantian morality (discussed in the final section of Spirit) -- the capacity to see things, as it were, from a “universal” point of view -- is bound up with the attitude implicitly adopted in engaging with spirit's “alienations.”

We might think that if *Kant* had written the *Phenomenology*, he would have ended it at chapter 6 with the modern moral subject as the telos of the story. For Kant, the practical knowledge of morality, orienting one within the *noumenal* world, exceeds the scope of theoretical knowledge which had been limited to phenomena. Hegel, however, thought that philosophy had to unify theoretical and practical knowledge,

and so the *Phenomenology* has further to go. Again, this is seen differently by traditionalists and revisionists. For traditionalists, Chapters 7, “Religion” and 8, “Absolute Knowing,” testify to Hegel's disregard for Kant's critical limitation of theoretical knowledge to empirical experience. Revisionists, on the other hand, tend to see Hegel as furthering the Kantian critique into the very coherence of a conception of an “in-itself” reality which is beyond the limits of our theoretical (but not practical) cognition. Rather than understand “absolute knowing” as the achievement of some ultimate “God's-eye view” of everything, the philosophical analogue to the connection with God sought in religion, revisionists see it as the accession to a mode of self-critical thought that has finally abandoned all non-questionable mythical “givens,” and which will only countenance reason-giving argument as justification. However we understand this, absolute knowing is the standpoint to which Hegel has hoped to bring the reader in this complex work. This is the “standpoint of science,” the standpoint from which philosophy proper commences, and it commences in Hegel's next book, the *Science of Logic*.

3.2 Science of Logic

Hegel's *Science of Logic*, the three constituent “books” of which appeared in 1812, 1813, and 1816 respectively, is a work that few contemporary logicians would recognise as a work of *logic*, but it is not meant as a treatise in formal (or “general”) logic. Rather, its provenance is to be found in what Kant had called “transcendental logic,” and which is more akin to what now is termed “epistemic” logic. In this sense it stands as a successor to Kant's “transcendental deduction of the categories” in the *Critique of Pure Reason* in which Kant attempted to “deduce” a list of those non-empirical concepts, the “categories,” which he believed to be presupposed by the empirical judgments of finite, discursive knowers like ourselves.

A glance at the table of contents of *Science of Logic* reveals the same triadic structuring noted in the *Phenomenology*. At the highest level of its branching structure there are three “books,” devoted to the doctrines of “being,” “essence,” and “concept” respectively. In turn, each book has three sections, each section containing three chapters, and so on. In general each of these nodes deals with some particular category or “thought determination,” sometimes the first subheading under a node having the same name as the node itself. To some extent, the treatment of the syllogism found in Book 3 (and following Aristotle's three-termed schematism of the syllogistic structure) might be seen as providing a retrospective justification for this structuring, Hegel's idea being that all rigorous thought about anything must grasp it in terms of the fundamental thought determinations of “singularity,” “particularity,” and “universality.” (This combination may, in fact, reflect the post-Kantians' re-interpretation of Kant's taxonomy of the basic components of cognition -- the division of mental representation into “singular” intuitions and “general” concepts. Fichte had understood that Kant equivocates over the relation of “sensation” to “intuition” : sometimes Kant treats sensations as *parts of* intuitive representations (their “matter”) and sometimes as *non-representational* states of the subject somehow “corresponding to” such matter. Kant's two-termed account therefore gets rearticulated as a three-termed account. In the later nineteenth century, no less a logician than Charles Sanders Peirce came to a similar idea about the fundamentally *trinary* structure of the categories of thought.)

Reading into the first chapter of Book 1, “Being,” it is quickly seen that the *Logic* repeats the movements of the first chapters of the *Phenomenology*, now, however, at the level of “thought” rather than conscious experience. Thus “being” is the thought determination with which the work commences because it at first seems to be the most “immediate,” fundamental determination characterising any possible thought content at all. It apparently has no internal structure (in the way that “bachelor,” say, has a structure containing further concepts “male” and “unmarried"). Again parallel to the *Phenomenology*, it is the effort of thought to make such contents explicit that both undermines them and brings about a new contents. “Being” *seems* “immediate” but reflection reveals that it itself is, in fact, only meaningful in opposition to another concept, “nothing.” In fact, the attempt to think “being” *as* immediate, and so as not *mediated* by its opposing concept “nothing,” has so deprived it of any determinacy or meaning at all that it effectively *becomes* nothing. That is, on reflection it is grasped as *having passed over* into its “negation” . Thus, while “being” and “nothing” *seem* both absolutely distinct and opposed, from another point of view they appear *the same* as no criterion can be invoked which differentiates them. The only way out of this paradox is to posit a third category, “becoming,” which seems to save thinking from paralysis because it accommodates both concepts: “becoming” contains “being” and “nothing” since when something “becomes” it passes, as it were, between nothingness and being. That is, when something *becomes* it seems to posses aspects of both *being* and *nothingness*.

In general this is how the *Logic* proceeds: seeking its most basic and universal determination, thought posits a category to be reflected upon, finds then that this collapses due to a contradiction generated, but then seeks a further category with which to make retrospective sense of that contradiction. This new category is more complex as it has internal structure in the way that “becoming” contains “being” and “nothing” as *moments*. But in turn the new category will generate some further contradictory negation and again the demand will arise for a further concept which will reconcile these opposed concepts by incorporating *them* as moments.

In this way the categorical infrastructure to thought becomes unpacked with only the use of those resources available to thought itself, its capacity to make its contents determinate (i.e., clear and distinct) and its refusal to tolerate contradiction. As has been mentioned, Hegel's logic might best be considered as a “transcendental” not a “formal” logic. Rather than treating the pure “form” of thought that has been abstracted from any possible content, transcendental logic treats thought that already possesses a certain type of content that Kant had called (predictably) “transcendental content.” This was that non-empirical but nevertheless intuitive element of “content” that was implicit in our thought, given that it was the thought of a particular *kind* of thinker, whose cognition about the world was restricted to the capacity to apply general concepts to singular and immediate empirical “intuitions.” It would seem to be this difference to traditional formal logic that underlies the contrast between the conceptual structure generated here, and that of the traditional “Tree of Porphyry” that results from the Platonic “method of division.” In the traditional structure, a more general concept is divided into more specific ones by means of some differentiating characteristic, in the way, for example, that the more general concept “animal” can be differentiated into “vertebrates” and “invertebrates.” In such a structure, the direction of conceptual *specificity*, and conceptual *containment* are reversed: a concept at any level will “contain,” as sub-concepts, all members of the chain of more abstract concepts standing “above” it. Thus if the concept “animal” is divided into the contraries “vertebrate” and “invertebrate,” each will in turn “contain” the

superordinating concept “animal” and thereby in turn contain every concept that is contained within (and stands above) “animal.” In contrast, in Hegel's conceptual structure, reflection on a concept produces its negation in a type of *internal* division, and then both concept and negation become contained as “moments” in the more specific concept that is posited to resolve the paradox of that internal negation.

If Hegel's is a transcendental logic, however, it is clearly different from that of Kant's. For Kant, transcendental logic was the logic governing the thought of *finite* thinkers like ourselves, whose cognition was constrained by the necessity of applying general discursive *concepts* to the singular contents given in sensory *intuitions*, and he kept open the possibility that there could be a kind of thinker not so constrained -- God, for example, whose thought could apply directly to the world in a type of “intellectual” intuition. Again, opinions divide as to how Hegel's approach to logic relates to that of Kant. Traditionalists see Hegel as treating the finite thought of individual human discursive intellects as a type of “distributed” vehicle for the classically conceived *infinite* and *intuitive* thought of God. Non-traditionalists, in contrast, see the post-Kantians as removing the last residual remnant of the mythical idea of transcendent godly thought from Kant's approach. On their account, the very opposition that Kant has between finite human thought and infinite godly thought is suspect, and the removal of this mythical obstacle allows an expanded role for “transcendental content.” Regardless of how we interpret this however, it is important to grasp that for Hegel logic is not simply a science of the *form* of our thoughts but is also a science of actual “content” as well, and as such is a type of *ontology*. Thus it is not just about the concepts “being,” “nothing,” “becoming” and so on, but about *being*, *nothing*, *becoming* and so on, *themselves*. This in turn is linked to Hegel's radically non-representationalist (and in some sense “direct realist”) understanding of thought. The world is not “represented” in thought by a type of “proxy” standing for it, but rather is presented, exhibited, or made manifest in it. (In recent analytic philosophy, John McDowell has presented an account of thought with this type of character, and has explicitly drawn a parallel to the approach of Hegel.)

The thought determinations of Book 1 lead eventually into those of Book 2, “The Doctrine of Essence.” Naturally the structures implicit in “essence” thinking are more developed than those of “being” thinking. Crucially, the contrasting pair “essence” and “appearance” allow the thought of some underlying reality which manifests itself through a different overlying appearance, a relation not able to be captured in the simpler “being” structures. Given the ontological dimension of Hegel's logic, its various stages are meant to coincide roughly with actual ontologies encountered in a history of metaphysics. Thus the metaphysics of Parmenides and Heraclitus, for example, line up with the thought determinations “being” and “becoming” at the beginning of Being-logic while Essence-logic culminates in concepts bound up with modern forms of substance metaphysics as found in Spinoza and Leibniz.

Book 3, “The Doctrine of Concept” effects a shift from the “Objective Logic” of Books 1 and 2, to “Subjective Logic,” and metaphysically coincides with a shift to the modern subject-based ontology of Kant. Just as Kantian philosophy is founded on a conception of objectivity secured by conceptual coherence, Concept-logic commences with the concept of “concept” *itself*! While in the two books of objective logic, the movement had been between particular concepts, “being,” “nothing,” “becoming” etc., in the subjective logic, the conceptual relations are grasped at a meta-level, such that the concept “concept” treated in Chapter 1 of section 1 (“Subjectivity”) passes over into that of “judgment” in

Chapter 2, as judgments are the larger wholes within which concepts themselves get related to each other. When the anti-foundationalism and holism of the *Phenomenology* is recalled, it will come as no surprise that the concept of judgment passes over into that of “syllogism”: for Hegel just as a concept gains its determinacy in the context of the judgments within which it is applied, so too do judgements gain their determinacy within larger patterns of *inference*. When Hegel declares the syllogism to be “the truth” of the judgment, he might be thought, as has been suggested by Robert Brandom, to be advocating a view somewhat akin to contemporary “inferentialist” approaches to semantics. On these approaches, an utterance gains its semantic content not from any combination of its already meaningful sub-sentential components, but from the particular inferential “commitments and entitlements” acquired when it is offered to others in practices presupposing the *asking for* and *giving of reasons*. Thought of in terms of the framework of Kant's “transcendental logic,” Hegel's position would be akin to allowing *inferences* -- “syllogisms” -- a role in the determination of “transcendental content,” a role which inference definitely does *not* have in Kant.

We might see then how the different ways of approaching Hegel's logic will be reflected in the interpretation given to the puzzling claim in Book 3 concerning the syllogism becoming “concrete” and “pregnant with” a content that has necessary existence. In contrast with Kant, Hegel seems to go beyond a “transcendental deduction” of the *formal* conditions of experience and thought and to a deduction of their *material* conditions. Traditionalists will see here something akin to the “ontological argument” of medieval theology in which the *existence* of something seems to have been necessitated by its concept -- an argument undermined by Kant's criticism of the treatment of *existence* as a predicate. In Hegel's version, it would be said, the objective existence that God achieves in the world has been necessitated by his essential self-consciousness. The revisionist reading, in contrast, would have to interpret this aspect of Hegel's logic differently.

As already noted, for Hegel, the logic of *inference* has a “transcendental content” in a way analogous to that possessed by the logic of *judgment* in Kant's transcendental logic. It is this which is behind the idea that the treatment of the formal syllogisms of inference will lead to a consideration of those syllogisms as “pregnant with content.” But for logic to be truly ontological a further step “beyond” Kant is necessary. For the post-Kantians, Kant had been mistaken in restricting the conditions of experience and thought to a “subjective” status. Kant's idea of our knowledge as restricted to the world as it is *for us* requires us to have a concept of the noumenal as that which cannot be known, the concept “noumenon” playing the purely *negative* role of giving a determinate sense to “phenomenon” by specifying its limits. That is, for Kant we need to be able to think of our experience and knowledge *as* finite and conditioned, and this is achieved in terms of a concept of a realm *we cannot know*. But, the post-Kantian objection goes, if the concept “noumenon” is to provide some sort of boundary to that of “phenomenon,” then it cannot be the *empty* concept that Kant supposed. Only a concept *with a content* can determine the limits of the content of some another concept (as when our empirical concept of “river,” for example, is made determinate by opposing empirical concepts like “stream” or “creek”). The positing of a noumenal realm must be the positing of a realm about which we can have *some* understanding.

This need felt by the post-Kantians for having a contentful concept of the “noumenal” or the “in itself” can also be seen from the inverse perspective. For Kant, sensation testifies to the existence of an

objective noumenal world beyond us, but *this* world cannot be known *as such*; we can only know that world as it appears to us from within the constraints of the subjective conditions of our experience and thought. But for Hegel this is to attribute to a wholly inadequate form of knowledge -- sensation or feeling -- a power that is being denied to a much *better* form of knowledge -- that articulated by *concepts*. To think that our inarticulate sensations or feelings give us a *truer* account of reality than that of which we are capable via the scientific exercise of conceptualised thought indicates a type of irrationalist potential within Kantian thought, a potential that Hegel thought was being realised by the approach of his romantic contemporaries. The rational kernel of Kant's approach, then, had to be carried beyond the limits of a method in which the conditions of thought and experience were regarded as *merely* subjective. Rather than restrict its scope to “formal” conditions of experience and thought, it had to be understood as capable of revealing the *objective* or material conditions. Transcendental logic must thereby become ontological. It may be significant here that, as some recent studies of Kant's own later work (the *Opus Postumum*) suggest, Kant himself seems to have revised his own approach such that something like a deduction of the material conditions of thought was now considered as the proper province of transcendental philosophy.

3.3 Philosophy of Right

Like the *Science of Logic*, the *Encyclopaedia of the Philosophical Sciences* is itself divided into three parts: a *Logic*; a *Philosophy of Nature*; and a *Philosophy of Spirit*. The same triadic pattern in the *Philosophy of Spirit* results in the philosophies of *subjective* spirit, *objective* spirit, and *absolute* spirit. The first of these constitutes Hegel's philosophy of mind, the last, his philosophy of art, religion, and philosophy itself. The philosophy of *objective spirit* concerns the objective patterns of social interaction and the cultural institutions within which “spirit” is objectified. The book entitled *Elements of the Philosophy of Right* which Hegel published as a textbook for his lectures at Berlin essentially corresponds to a more developed version of the section on “Objective Spirit” in the *Philosophy of Spirit*.

The *Philosophy of Right* (as it is more commonly called) can, and has been, read as a political philosophy which stands independently of the system, but it is clear that Hegel intended it to be read against the background of the developing conceptual determinations of the *Logic*. The text proper starts from the conception of a singular willing subject (grasped from its own first-person point of view) as the bearer of “abstract right.” While this conception of the individual willing subject with some kind of fundamental right is in fact the starting point of many modern political philosophies (such as that of Locke, for example) the fact that Hegel commences here does not testify to any ontological assumption that the consciously willing and right-bearing individual is the basic *atom* from which all society can be understood as constructed -- an idea at the heart of standard “social contract” theories. Rather, this is merely the most “immediate” starting point of Hegel's presentation and corresponds to analogous starting places of the *Logic*. Just as the categories of the *Logic* develop in a way meant to demonstrate that what had at the start been conceived as simple is in fact only made determinate in virtue of its being part of some larger structure or process, here too it is meant to be shown that any simple willing and right-bearing subject only gains *its* determinacy in virtue of a place it finds for itself in a larger *social*, and ultimately *historical*, structure or process. Thus even a contractual exchange (the minimal social interaction for contract theorists) is not to be thought simply as an occurrence consequent upon the

existence of two beings with natural wants and some natural calculative rationality; rather, the system of interaction within which individual exchanges take place (the economy) will be treated holistically as a culturally-shaped form of social life within which the actual wants of individuals as well as their reasoning powers are given determinate forms.

Here too it becomes apparent in Hegel's treatment of property and the exchange contract that the notion of *recognition* plays a crucial role in his general conception of the relation of individuals to each other and to society as a whole. A contractual exchange of commodities between two individuals itself involves an implicit act of recognition in as much as each, in giving something to the other in exchange for what they want, are thereby recognizing them *as* a proprietor of that thing, or, more properly, of the inalienable *value* attaching to it. By contrast, such proprietorship would be *denied* rather than recognised in fraud or theft -- forms of “wrong” (*Unrecht*) in which right is negated rather than acknowledged or posited. Thus what differentiates property from mere *possession* is that it is grounded in a relation of reciprocal recognition between two willing subjects. Moreover, it is in the exchange relation that we can see what it means for Hegel for individual subjects to share a “common will” -- an idea which will have important implications with respect to the difference of Hegel's conception of the state from that of Rousseau. Such an interactive constitution of the *common will* means that for Hegel such an identity of will is achieved *because of* not *in spite of* a co-existing *difference* between the particular wills of the subjects involved: while contracting individuals both “will” *the same* exchange, at a more concrete level, they do with different ends in mind. Each wants something different *from* the exchange.

Hegel passes from the abstract individualism of “Abstract Right” to the social determinacies of *“Sittlichkeit”* or “Ethical Life” via considerations first of “wrong” (the negation of right) and its punishment (the negation of wrong, and hence the “negation of the negation” of the original right), and then of “morality,” conceived more or less as an internalisation of the external legal relations. Consideration of Hegel's version of the retributivist approach to punishment affords a good example of his use of the logic of “negation.” In punishing the criminal the state makes it clear to its members that it is the acknowledgment of right *per se* that is essential to developed social life: the significance of “acknowledging another's right” in the contractual exchange cannot be, as it at first might have appeared to the participants, simply that of being a way of each getting what he or she wants *from the other*. Hegel's treatment of punishment also brings out the continuity of his way of conceiving of the structure and dynamics of the social world with that of Kant, as Kant too, in his *Metaphysics of Morals* had employed the idea of the state's punitive action as a *negating* of the original criminal act. Kant's idea, conceived on the model of the physical principle of action and reaction, was structured by the category of “community” or reciprocal interaction, and was conceived as involving what he called “real opposition.” Such an idea of opposed dynamic forces seems to form something of a model for Hegel's idea of contradiction and the starting point for his conception of reciprocal *recognition*. Nevertheless, clearly Hegel articulates the structures of recognition in more complex ways than those derivable from Kant's category of community.

First of all, in Hegel's analysis of *Sittlichkeit* the type of sociality found in the market-based “civil society” is to be understood as dependent upon and in contrastive opposition with the more immediate form found in the institution of the family -- a form of sociality mediated by a quasi-natural inter-

subjective recognition rooted in sentiment and feeling: love. In the family the particularity of each individual tends to be absorbed into the social unit, giving this manifestation of *Sittlichkeit* a one-sidedness that is the inverse of that found in market relations in which participants grasp themselves in the first instance as separate individuals who then enter into relationships that are external to them.

These two opposite but interlocking principles of social existence provide the basic structures in terms of which the component parts of the modern state are articulated and understood. As both contribute particular characteristics to the subjects involved in them, part of the problem for the rational state will be to ensure that each of these two principles mediate the other, each thereby mitigating the *one-sidedness* of the other. Thus, individuals who encounter each other in the “external” relations of the market place and who have their subjectivity shaped by such relations also belong to families where they are subject to opposed influences. Moreover, even within the ensemble of production and exchange mechanisms of civil society individuals will belong to particular “estates” (the agricultural estate, that of trade and industry, and the “universal estate” of civil servants), whose internal forms of sociality will show family-like features.

Although the actual details of Hegel's “mapping” of the categorical structures of the *Logic* onto the *Philosophy of Right* are far from clear, the general motivation is apparent. As has been mentioned above, Hegel's logical categories can be read as an attempt to provide a schematic account of the material (rather than formal) conditions required for developed self-consciousness. Thus we might regard the various “syllogisms” of Hegel's *Subjective Logic* as attempts to chart the skeletal structures of those different types of recognitive inter-subjectivity necessary to sustain various aspects of rational cognitive and conative functioning (“self-consciousness”). From this perspective, we might see his “logical” schematisation of the modern “rational” state as a way of displaying just those sorts of institutions that a state must provide if it is to answer Rousseau's question of the form of association needed for the formation and expression of the “general will.”

Concretely, for Hegel it is representation of the estates within the legislative bodies that is to achieve this. As the estates of civil society group their members according to their common interests, and as the deputies elected from the estates to the legislative bodies give voice to those interests within the deliberative processes of legislation, we might see how the outcome of this process might be considered to give expression to the general interest. But Hegel's “republicanism” is here cut short by his invocation of the familial principle: such representative bodies can only provide the *content* of the legislation to a *constitutional monarch* who must add to it the form of the royal decree -- an individual “I will ….” To declare that for Hegel the monarch plays only a “symbolic” role here is to miss the fundamentally idealist complexion of his political philosophy. The expression of the general will in legislation cannot be thought of as an outcome of some quasi-mechanical process: it must be “willed.” If legislation is to express the general will, citizens must recognize it as expressing *their* wills; and this means, recognising it *as* willed. The monarch's explicit “I will” is thus needed to close this recognitive circle, lest legislation look like a mechanical compromise resulting from a clash of interests, and so as actively *willed* by nobody. Thus while Hegel is critical of standard “social contract” theories, his own conception of the state is still clearly a complicated transformation of those of Rousseau and Kant.

Perhaps one of the most influential parts of Hegel's *Philosophy of Right* concerns his analysis of the contradictions of the unfettered capitalist economy. On the one hand, Hegel agreed with Adam Smith that the interlinking of productive activities allowed by the modern market meant that “subjective selfishness” turned into a ”contribution towards the satisfaction of the needs of everyone else.” But this did not mean that he accepted Smith's idea that this “general plenty” produced thereby *diffused* (or “trickled down”) though the rest of society. From within the type of consciousness generated within civil society, in which individuals are grasped as “bearers of rights” abstracted from the particular concrete relationships to which they belong, Smithean optimism may seem justified. But this simply attests to the one-sidedness of this type of abstract thought, and the need for it to be mediated by the type of consciousness based in the family in which individuals are grasped in terms of the way they *belong to* the social body. In fact, the unfettered operations of the market *produces* a class caught in a spiral of poverty. Starting from this analysis, Marx later used it as evidence of the need to abolish the individual proprietorial rights at the heart of Hegel's “civil society” and socialise the means of production. Hegel, however, did not draw this conclusion. His conception of the exchange contract as a form of recognition that played an essential role within the state's capacity to provide the conditions for the existence of rational and free-willing subjects would certainly prevent such a move. Rather, the economy was to be contained within an over-arching institutional framework of the state, and its social effects offset by welfarist state intervention.

Johann Gottlieb Fichte

Inspired by his reading of Kant, Johann Gottlieb Fichte (1762 - 1814) developed during the final decade of the eighteenth century a radically revised and rigorously systematic version of transcendental idealism, which he called *Wissenschaftslehre* of "Doctrine of Scientific Knowledge." Perhaps the most characteristic, as well as most controversial, feature of the *Wissenschaftslehre* (at least in its earlier and most influential version) is Fichte's effort to ground his entire system upon the bare concept of subjectivity, or, as Fichte expressed it, the "pure I." During his career at the University of Jena (1794-1799) Fichte erected upon this foundation an elaborate transcendental system that embraced the philosophy of science, ethics, philosophy of law or "right." and philosophy of religion.

1. Life and Work

Fichte was born May 19, 1762 in the village of Rammenau in the Oberlausitz area of Saxony. He was the eldest son in a family of poor and pious ribbon weavers. His extraordinary intellectual talent soon

brought him to the attention of a local baron, who sponsored his education, first in the home of a local pastor, then at the famous Pforta boarding school, and finally at the universities of Jena and Leipzig. With the death of his patron, Fichte was forced to discontinue his studies and seek his livelihood as a private tutor, a profession he quickly came to detest.

Following a lengthy sojourn in Zurich, were he met his future wife, Johanna Rahn, Fichte returned to Leipzig with the intention of pursuing a literary career. When his projects failed, he was again forced to survive as a tutor. It was in this capacity that he began giving lessons on the Kantian philosophy in the summer of 1790. This first encounter with Kant's writings produced what Fichte himself described as a "revolution" in his manner of thinking. Whereas he had formally been torn between, on the one hand, a practical commitment to the moral improvement of humanity and, on the other, a theoretical commitment to "intelligible fatalism," he found in the Critical philosophy a way of reconciling his "head" and "heart" in a system that could meet the highest intellectual standards without requiring him to sacrifice his belief in human freedom.

Fichte eventually made his way to Königsberg, where he lived for a few months. After a disappointing interview with Kant, he resolved to demonstrate his mastery of the latter's philosophy by writing a treatise on a theme as yet unaddressed by Kant: namely, the question of the compatibility of the Critical philosophy with any concept of divine revelation. In a few weeks Fichte composed a remarkable manuscript in which he concluded that the only revelation consistent with the Critical philosophy is the moral law itself. Kant was sufficiently impressed by the talent of this unknown and impoverished young man to offer to arrange for the publication of Fichte's manuscript, which was published by Kant's own publisher in 1792 under the title *Attempt at a Critique of All Revelation*. The first edition of this work, however, for reasons that have never been satisfactorily explained, appeared without the author's name and preface and was quickly and widely hailed as a work by Kant himself. When the true identity of its author was revealed, Fichte was immediately catapulted from total obscurity to philosophical celebrity.

Meanwhile, Fichte was once again employed as a private tutor, this time on an estate near Danzig, where he wrote several, anonymously published political tracts. The first of these was published in 1793 with the provocative title *Reclamation of the Freedom of Thought from the Princes of Europe, who have hitherto Suppressed it*. In the summer of 1793 Fichte returned to Zurich where he married his fiancé and oversaw the publication of the first two installments of his spirited *Contribution to the Rectification of the Public's Judgment of the French Revolution* (1793 and 1794). In this work he not only defended the principles (if not all the practices) of the French revolutionaries, but also attempted to outline his own democratic view of legitimate state authority and insisted on the right of revolution. Despite the fact that these political writings were published anonymously, the author's identity was widely known, and Fichte thereby acquired a reputation, not wholly deserved, as a radical "Jacobin."

Following the completion of these projects, Fichte devoted his time in Zurich to concentrated efforts to rethink and to revise his own philosophical position. While maintaining his allegiance to the new Critical or Kantian philosophy, Fichte was powerfully impressed by the efforts of K. L. Reinhold to provide the Critical philosophy with a new, more secure "foundation" and to base the entire system upon a single "first principle." At the same time, he became acquainted with the works of two authors who were

engaged in skeptical attacks upon the philosophies of both Kant and Reinhold: Solomon Maimon and G. E. Schulze ("Aenesidemus"). It was the need to respond to the sharp criticisms of these authors that eventually led Fichte to construct his own, unique version of transcendental idealism, for which, in the spring of 1794, he eventually coined the name *Wissenschaftslehre* ("Doctrine of Science" or "Theory of Scientific Knowledge").

It was at precisely this moment that he received an invitation to assume the recently vacated chair of Critical Philosophy at the University of Jena, which was rapidly emerging as the capital of the new German philosophy. Fichte arrived in Jena in May of 1794, and enjoyed tremendous popular success there for the next six years, during which time he laid the foundations and developed the first systematic articulations of his new system. Even as he was engaged in this immense theoretical labor, he also tried to address a larger, popular audience and also threw himself into various practical efforts to reform university life. As one bemused colleague observed, "his is a restless spirit; he thirsts for some opportunity to act in the world. Fichte wants to employ his philosophy to guide the spirit of his age." Indeed, a passionate desire to "have an effect" upon his own age remained a central feature of Fichte's character, most notably expressed a decade later in his celebrated *Addresses to the German Nation,* delivered in Berlin in 1806 during the French occupation. In Jena, this same desire is reflected in the enormously popular series of public lectures on "Morality for Scholars," which he began to deliver immediately upon his arrival in Jena. The first five of these lectures were published in 1794 under the title *Some Lectures concerning the Scholar's Vocation*.

Though Fichte has already hinted at his new philosophical position in his 1794 review of G. E,. Schulze's *Aenesidemus,* the first full-scale announcement of the same came in a short manifesto that he published as a means of introducing himself to his students and colleagues and attracting listeners to his lectures. (As an "extraordinary professor," Fichte was largely dependent upon fees paid by students attending his "private" lectures.) This manifesto, *Concerning the Concept of the Wissenschaftslehre* (1794), articulated some of the basic ideas of the new philosophy, but it mainly focused upon questions of systematic form and the foundations of the same.

Fichte's first truly systematic work was his *Foundation of the Entire Wissenschaftslehre* (1794/95). As the title implies, this work, which remains to this day Fichte's best-known philosophical treatise, was not meant to be a presentation of his entire system, but only of the rudiments or first principles of the same. In fact, Fichte had not originally intended to publish this work at all, which was written less than a year after his first tentative efforts to articulate for himself his new conception of transcendental philosophy. The *Foundation* was originally intended to be distributed, in fascicles, to students attending his private lectures during his first two semesters at Jena, where the printed sheets could be subjected to analysis and questions and supplemented with oral explanations. Because of the great interest in Fichte's new philosophy, however, he soon authorized a public edition of the same, in two volumes. Parts I and II of the *Foundation* were published in 1794 and Part II in 1795. In 1795 he also published a substantial supplement to the *Foundation,* under the title *Outline of the Distinctive Character of the Wissenschaftslehre with Respect to the Theoretical Faculty*. The title pages of all three of these publications, however, still stipulated that they were intended only as "a manuscript for the use of his listeners." (When, in 1802, Fichte issued a second, one-volume edition of the *Foundation* and *Outline*, in

1801, this subtitle was dropped.)

Dissatisfied with many features of his initial presentation of the "foundational" portion of his system and surprised and shocked by the virtually universal misunderstanding of his published *Foundation*, Fichte immediately set to work on an entirely new exposition of the same, which he repeated three times in his private lectures on "The Foundations of Transcendental Philosophy (*Wissenschaftslehre) nova methodo*" (1796/76, 1797/98, 1798/99). Though he intended to revise these lectures for serial publication under the title *An Attempt a New Presentation of the Wissenschaftslehre* in the *Philosophisches Journal einer Gesellschaft Teutscher Gelehrten*, of which he himself was by then co-editor, only the two Introductions to and the first chapter of this "New Presentation" ever appeared (1797/98).

Even as he was thoroughly revising his presentation of the foundational portion of his system, Fichte was simultaneously engaged in elaborating the various subdivisions or systematic branches of the same. As was his custom, he did this first in his private lectures and then in published texts based upon the same. The first such extension was into the realm of philosophy of law and social philosophy, which resulted in the publication of *Foundation of Natural Right in accordance with the Principles of the Wissenschaftslehre* (published in two volumes in 1796 and 1797). The second was into the realm of moral philosophy, which resulted in the publication of the *System of Ethical Theory in accordance with the Principles of the Wissenschaftslehre* (1798). At this point, Fichte's own plans called for him to extend his system into the realm of philosophy of religion. He announced lectures on this topic for the Spring Semester of 1799, but before he could commence these lectures, his career at Jena had come to an abrupt and unhappy conclusion in the wake of the so-called "Atheism Controversy" of 1798/99.

In 1798 Fichte published in his *Philosophical Journal* a brief essay "On the Basis of Our Belief in a Divine Governance of the World," in which he attempted to sketch some of his preliminary ideas on the topic indicated in the title and simultaneously to give the first clear public hint of the character of a philosophy of religion "in accordance with the principles of the *Wissenschaftslehre*." The occasion for this essay was another essay, published in the same issue of the *Philosophical Journal*, by K. L. Forberg. As it happened, these two essays provoked an anonymous author to publish a pamphlet charging the authors with atheism and demanding Fichte's dismissal from his post at Jena. The matter quickly escalated into a major public controversy which eventually led to the official suppression of the offending issue of the journal and to public threats by various German princes to prevent their students from enrolling at the University of Jena. The crisis produced by these actions and the growing number of publications for and against Fichte -- which included an intemperate *Appeal to the Public* by Fichte himself (1799), as well as a more thoughtful response entitled "From a Private Letter" (1799) - eventually provoked F. H. Jacobi to publish his famous "open letter" to Fichte, in which he equated philosophy in general and Fichte's transcendental philosophy in particular with "nihilism." As the public controversy unfolded, Fichte badly miscalculated his own position and was finally forced to resign his position at Jena and to flee to Berlin, where he arrived in the summer of 1799.

At this point, the Prussian capital had no university of its own, and Fichte was forced to support himself by giving private tutorials and lectures on the *Wissenschaftslehre* and by a new flurry of literary production, increasingly aimed at a large, popular audience. The first of these "popular" writings was a

brilliant presentation of some of the characteristic doctrines and conclusions of Fichte's system, with a strong emphasis upon the moral and religious character of the same. This work, *The Vocation of Man* (1800), which is perhaps Fichte's greatest literary achievements, was intended as an indirect response to Jacobi's public repudiation of the *Wissenschaftslehre*. That same year also saw the publication of a typically bold foray into political economy, *The Closed Commercial State*, in which Fichte propounds a curious blend of socialist political ideas and autarkic economic principles. Defending his philosophy against misunderstanding remained, however, Fichte's chief concern during this period, as is evidenced by the more direct response to Jacobi contained in his poignantly titled *Sun-Clear Report to the Public at Large concerning the Actual Character of the latest Philosophy: An Attempt to Force the Reader to Understand* (1801).

At the same time that he was addressing the public in this manner, Fichte was becoming ever more deeply engrossed in efforts to rethink and to rearticulate the very foundations of his system, beginning with his private lectures on the *Wissenschaftslehre* of 1801/2, and culminating in the three, radically new versions of the same produced during the year 1804. Indeed, he continued to produce new versions of the *Wissenschaftslehre* right up until his death. However, with the single exception of the extraordinarily condensed (and extraordinarily opaque) *Presentation of the General Outlines of the Wissenschaftslehre* (1810), none of these later versions of the *Wissenschaftslehre* was published during Fichte's lifetime. Some of them appeared, in severely edited form, in the collection of Fichte's *Works* published by his son several decades following his death, but most of them are only now being published for the first time in the critical edition of Fichte's writings produced by the Bavarian Academy of the Sciences. It appears that Fichte was so discouraged by the public reception of the first, 1794/95 presentation of the foundation of his system that he concluded that it was prudent to limit future new presentations of the same to the lecture hall and seminar room, where he could elicit reactions and objections from his listeners and respond immediately with the requisite corrections and clarifications. Be that as it may, Fichte never stopped trying to refine his philosophical insights and to revise his systematic presentation of the same. Their are more than a dozen different full-scale presentations or versions of the *Wissenschaftslehre*, most of which were written after his departure from Jena. "The *Wissenschaftslehre*" is not the name of a book; it is the name of a *system of philosophy*, one capable of being expounded in a variety of different ways.

In 1805 Fichte spend a semester as a professor at the University of Erlangen, but returned to Berlin in the fall of that year. The next year, 1806, he published in rapid succession three popular and well-received books, all of which were based upon earlier series of public lectures that he had delivered in Berlin: *On the Essence of the Scholar* (a reworking of some of the same themes first addressed in the similarly titled lectures of 1794); *The Characteristics of the Present Age* (an attempt to show the implications of his "system of freedom" for a speculative philosophy of history); and *Guide to the Blessed Life* (an eloquent and rather mystical treatise on philosophy and religion). Taken together, these three "popular" works are remarkable blends of speculative profundity and rhetorical eloquence.

With the entry of the French army of occupation into Berlin in 1806, Fichte joined the Prussian government in exile in Königsberg, where he delivered yet another course of lectures on the *Wissenschaftslehre* and wrote an important short book on *Machiavelli as Author* (1807), which defends a form of *Realpolitik* that at least appears to contrast quite starkly with the liberalism and political idealism

of Fichte's earlier political writings. Fichte soon returned to occupied Berlin, however, where, in the winter of 1807/8, he delivered his celebrated *Addresses to the German Nation* (published in 1808). Though these lectures later obtained a place of dubious honor as founding documents in the history of German nationalism, they are mainly concerned with the issue of national identity (and particularly with the relationship between language and nationality) and the question of national education (which is the main topic of the work) -- both understood as means toward a larger, cosmopolitan end.

Fichte had always had a lively interest in pedagogical issues and assumed a leading role in planning the new Prussian university to be established in Berlin (though his own detailed plans for the same were eventually rejected in favor of those put forward by Wilhelm von Humboldt). When the new university finally opened in 1810, Fichte was the first head of the philosophical faculty as well as the first elected rector of the university. His final years saw no diminishment in the pace either of his public activity or of his philosophical efforts. He continued to produce new lectures on the foundations and first principles of his system, as well as new introductory lectures on philosophy in general ("Logic and Philosophy" [1812] and "The Facts of Consciousness" [1813]), political philosophy ("System of the Theory of Right" [1812] and ‘Theory of the State’ [1813]) and ethics ("System of Ethical Theory" [1812]). As presaged perhaps by his earlier book on Machiavelli, these late forays into the domain of practical philosophy betray a far darker view of human nature and defend a more authoritarian view of the state than anything to be found in Fichte's earlier, published writings on these subject.

In 1813 Fichte canceled his lectures so that his students could enlist in the "War of Liberation" against Napoleon, of which Fichte himself proved to be an indirect casualty. From his wife, who was serving as a volunteer nurse in a Berlin military hospital, he contracted a fatal infection of which he died on January 29, 1814.

2. Fichte's Philosophical Project

The primary task of Fichte's system of philosophy (the *Wissenschaftslehre*) is to reconcile freedom with necessity, or, more specifically, to explain how freely willing, morally responsible agents can at the same time be considered part of a world of causally conditioned material objects in space and time. Fichte's strategy for answering this question -- at least in his early writings, which are the ones upon which his historical reputation as a philosopher has (at least until recently) been grounded and hence are the ones to be expounded here -- was to begin simply with the ungrounded assertion of the subjective spontaneity and freedom (infinity) of the I and then to proceed to a transcendental derivation of objective necessity and limitation (finitude) as a condition necessary for the possibility of the former. This is the meaning of his description, in his "First Introduction to the *Wissenschaftslehre*," of philosophy's task as that of "displaying the foundation of experience" or "explaining the basis of the system of representations accompanied by a feeling of necessity." Fichte derived this conception of the task and strategy of philosophy from his study of Kant, and no matter how far his own system seemed to diverge from "the letter" of the Critical philosophy, Fichte always maintained that it remained true to "the spirit" of the same. Central to this "spirit," for Fichte, is an uncompromising insistence upon the practical certainty of human freedom and a thoroughgoing commitment to the task of providing a transcendental account of

ordinary experience that could explain the objectivity and necessity of theoretical reason (cognition) in a manner consistent with the practical affirmation of human liberty. Though Fichte attributed the discovery of this task to Kant, he believed that it was first accomplished successfully only in the *Wissenschaftslehre*, which he therefore described as the first "system of human freedom."

In an effort to clarify the task and method of transcendental philosophy, Fichte insisted upon the sharp distinction between the "standpoint" of natural consciousness (which it is the task of philosophy to "derive," and hence to "explain") and that of transcendental reflection, which is the standpoint required of the philosopher. He thus insisted that there is no conflict between transcendental idealism and the commonsense realism of everyday life. On the contrary, the whole point of the former is to demonstrate the necessity and unavailability of the latter.

However "Kantian" in spirit Fichte's enterprise might have been, he was at the same time all too keenly aware of what he considered to be certain glaring weaknesses and inadequacies in Kant's own execution of this project. Taking to heart the criticisms of such contemporaries as F. H. Jacobi, Salomon Maimon, and G. E. Schulze, Fichte propounded a radically revised version of the Critical philosophy. First of all, he argued that the very concept of a "thing in itself," understood as a mind-independent, external "cause" of sensations, is indefensible on Critical grounds. In addition, he maintained that Kant's denial of the possibility of "intellectual intuition," though certainly justified as a denial of the possibility of any non-sensory awareness of external objects, is nevertheless difficult to reconcile with certain other Kantian doctrines regarding the I's immediate presence to itself both as a (theoretically) cognizing subject (the doctrine of the transcendental apperception) and as a (practically) striving moral agent (the doctrine of the categorical imperative).

His study of the writings of K. L. Reinhold convinced Fichte that the systematic unity of the Critical philosophy -- specifically, the unity of theoretical and practical reason, of the First and Second *Critiques* -- was insufficiently evident in Kant's own presentation of his philosophy and that the most promising way to display the unity in question would be to provide both theoretical and practical philosophy with a common foundation. The first task for philosophy, Fichte therefore concluded, is to discover a single, self-evident starting point or first principle from which one could then somehow "derive" both theoretical and practical philosophy, which is to say, our experience of ourselves as finite cognizers and as finite agents. Not only would such a strategy guarantee the systematic unity of philosophy itself, but, more importantly, it would also display what Kant hinted at but never demonstrated: viz., the underlying unity of reason itself.

Since it is a central task of philosophy, so construed, to establish the very possibility of any knowledge or science (*Wissenschaft*) whatsoever, Fichte proposed to replace the disputed term "philosophy" (or "love of wisdom") with the new term *Wissenschaftslehre* or ‘Theory or Science’ - a name intended to highlight the distinctively "second order" character of philosophical reflection. Though Fichte's proposal never caught on as a general name for what was once called "philosophy," it did become the universally acknowledged name for his own distinctive version of transcendental idealism. Here again, it important to keep in mind that "*Wissenschaftslehre"* is not the name of any particular Fichtean treatise, but is instead the general name for his entire system or project - an allegedly all-encompassing system that

consists of a number of interrelated parts or systematic subdisciplines and an overarching project that could and would be expounded in a series of radically different presentations, employing a bewildering variety of systematic vocabularies.

3. The Starting Point of the Jena *Wissenschaftslehre*

In order to construct any genuine philosophy of freedom, maintained Fichte, the reality of freedom itself must simply be presupposed and thus treated as an incontrovertible "fact of reason" in the Kantian sense. This, of course, is not to deny the possibility of raising skeptical, theoretically grounded objections to such claims; on the contrary, it was the very impossibility of any theoretically satisfactory refutation of skepticism concerning the reality of freedom that led Fichte to affirm the inescapable "primacy of the practical" with respect to the selection of one's philosophical starting point.

To the extent that any proposed first principle of philosophy is supposed to be the first principle of all knowledge and hence of all argument, it clearly cannot be derived from any higher principle and hence cannot be established by any sort of reasoning. Furthermore, Fichte maintained that there are two and only two possible starting points for the philosophical project of "explaining" experience: namely, the concept of pure selfhood (which Fichte associated with pure freedom) and that of pure thinghood (which Fichte associated with utter necessity) -- neither of which can be warranted, qua philosophical starting point, by a direct appeal to experience, and each of which can be arrived at only by a self-conscious act of philosophical *abstraction* from ordinary experience (within which freedom and necessity, subject and object, are invariably joined as well as distinguished).

The two rival philosophical strategies made possible by these opposed starting points are unforgettably limned by Fichte in his two 1797 "Introductions to the *Wissenschaftslehre*," in which he characterizes the sort of philosophy that begins with the pure I as "idealism" and that which begins with the thing in itself as "dogmatism." Since, according to Fichte's earlier argument in *Concerning the Concept of the Wissenschaftslehre*, a unified system of philosophy can have one and only one first principle, and since there are two and only two possible first principles, then it follows that no "mixed" system of idealism/dogmatism is possible. Moreover, since dogmatism, as understood by Fichte, unavoidably implies a strict form of determinism or "intelligible fatalism," whereas idealism is, from the start, committed to the reality of human freedom, it is also practically impossible to reach any sort of "compromise" between two such radically opposed systems.

Though Fichte conceded that neither dogmatism nor idealism could directly refute its opposite and thus recognized that the choice between philosophical starting points could never be resolved on purely theoretical grounds, he nevertheless denied that any dogmatic system, that is to say, any system that commences with the concept of sheer objectivity, could ever succeed in accomplishing what was required of all philosophy. Dogmatism, he argued, could never provide a transcendental deduction of ordinary consciousness, for, in order to accomplish this, it would have to make an illicit leap from the realm of

"things" to that of mental events or "representations" [*Vorstellungen*]. Idealism, in contrast, at least when correctly understood as the kind of Critical idealism that demonstrates that the intellect itself most operate in accordance with certain necessary laws, can -- at least in principle -- accomplish the prescribed task of philosophy and explain our experience of objects ("representations accompanied by a feeling of necessity") in terms of the necessary operations of the intellect itself, and thus without having to make an illicit appeal to things in themselves. To be sure, one cannot decide in advance whether or not any such deduction of experience from the mere concept of free self-consciousness is *actually* possible. This, Fichte conceded, is something that can be decided only after the construction of the system in question. Until then, it remains a mere *hypothesis* that the principle of human freedom, for all of its practical certainty, is also the proper starting point for a transcendental account of objective experience.

It must be granted that the truth of the *Wissenschaftslehre's* starting point cannot be established by any philosophical means, including its utility as a philosophical first principle. On the contrary -- and this is one of Fichte's most characteristic and controversial claims -- one already has to be convinced, on wholly extra-philosophical grounds, of the reality of one's own freedom *before* one can enter into the chain of deductions and arguments that constitute the *Wissenschaftslehre*. This is the meaning of Fichte's oft-cited assertion that "the kind of philosophy one chooses depends upon the kind of person one is." The only compelling reason why the transcendental idealist comes to a stop with -- and thus begins his system with -- the proposition that "the I freely posits itself" is therefore not because he is unable to entertain theoretical doubts on this score nor because he is simply unable to continue the process of reflective abstraction. Instead, he appeals to a principle eloquently expressed by Fichte in his essay "On the Basis of Our Belief in a Moral Governance of the World," namely: "I cannot go beyond this standpoint because I am not permitted to do so." It is precisely because the categorical imperative is in this way invoked to secure the first principle of his entire system that Fichte felt entitled to make the rather startling claim that the *Wissenschaftslehre* is the only system of philosophy that "accords with duty."

4. Systematic Overview of the Jena *Wissenschaftslehre*

4.1 The "Foundation"

The published presentation of the first principles of the Jena *Wissenschaftslehre* commences with the proposition, "the I posits itself"; more specifically, "the I posits itself as an I." Since this activity of "self-positing" is taken to be the fundamental feature of I-hood in general, the first principle asserts that "the I posits itself as self-positing." Unfortunately, this starting point is somewhat obscured in Part I of the *Foundation of the Entire Wissenschaftslehre* by a difficult and somewhat forced attempt on Fichte's part to connect this starting point to the logical law of identity, as well as by the introduction of two additional "first principles," corresponding to the logical laws of non-contradiction and sufficient reason. (Significantly, this distraction is eliminated entirely in the 1796/99 *Wissenschaftslehre nova methodo*, which begins with the simple "postulate" or "summons" to the reader: "think the I, and observe what is involved in doing this.")

"To posit" (*setzen*) means simply "to be aware of," "to reflect upon," or "to be conscious of"; this term does not imply that the I must simply "creates" its objects of consciousness. The principle in question simply states that the essence of I-hood lies in the assertion of ones own self-identity, i.e., that consciousness presupposes self-consciousness (the Kantian "I think," which must, at least in principle, be able to accompany all our representations). Such immediate self-identify, however, cannot be understood as a psychological "fact," no matter how privileged, nor as an "action" or "accident" of some previously existing substance or being. To be sure, it is an "action" of the I, but one that is identical with the very existence of the same. In Fichte's technical terminology, the original unity of self-consciousness is to be understood as both an action and as the product of the same: as a *Tathandlung* or "fact/act," a unity that is presupposed by and contained within every fact and every act of empirical consciousness, though it never appears as such therein.

This same "identity in difference" of original self-consciousness might also be described as an "intellectual intuition," inasmuch as it involves the *immediate* presence of the I to itself, prior to and independently of any sensory content. To be sure, such an "intellectual intuition" never occurs, as such, within empirical consciousness; instead, it must simply be presupposed (that is, "posited") in order to explain the possibility of actual consciousness, within which subject and object are always already distinguished. The occurrence of such an original intellectual intuition is itself inferred, not intuited.

Unfortunately, Fichte confuses matters by sometimes using the term "inner" or "intellectual intuition" to designate something else entirely: namely, the act of *philosophical reflection* or purified self-observation through which the philosopher becomes conscious of the transcendental conditions for the possibility of ordinary experience -- among which, of course, is the occurrence of the "original" intellectual intuition as a *Tathandlung*. On other occasions, he employs the term "intellectual intuition" in yet another sense: namely, to designate our direct, practical awareness within everyday life of our moral obligations (categorical imperative qua "*real* intellectual intuition"). Given the subsequent abuse of this term by Schelling and the romantics, as well as the confusion that one sometimes finds among expositors of Fichte on this issue, it is crucial to recognize systematic ambiguity of the term "intellectual intuition" in Fichte's own writings.

A fundamental corollary of Fichte's understanding of I-hood (*Ichheit*) as a kind of *fact/act* is his denial that the I is originally any sort of "thing" or "substance." Instead, the I is simply what it posits itself to be, and thus its "being" is, so to speak, a consequence of its self-positing, or rather, is co-terminus with the same. The first principle of the Jena *Wissenschaftslehre* is thus equally "practical" and "theoretical," insofar as the act described by this principle is a "doing" as well as a "knowing," a deed as well as a cognition. Thus the problematic unity of theoretical and practical reason is guaranteed from the start, inasmuch as this very unity is a condition for the possibility of self-consciousness.

After establishing the first principle and conceiving the act expressed therein, the philosophical task is then to discover what other acts must necessarily occur as conditions for the possibility of the original, "simply posited," first act and then to do the same for each of these successively discovered acts (or the theorems in which they are formulated). By continuing in this manner, one will, according to Fichte,

finally arrive at a complete deduction of the a priori structure of ordinary experience or, what amount to the same thing, a complete inventory of the "original acts of the mind." This is precisely the task of the first or "foundational" portion of the Jena system.

Just as we are never directly aware of the original act of self-positing with which the system commences, so are we also unaware -- except, of course, from the artificial standpoint of philosophical reflection -- of each of these additional "necessary but unconscious" acts that are derived as conditions necessary for the possibility of the originally posited act of self-positing. Furthermore, though we must, due to the discursive character of reflection itself, distinguish each of these acts from the others that it is conditioned by and that are, in turn, conditioned by it, none of these individual acts actually occurs in isolation from all of the others. Transcendental philosophy is thus an effort to *analyze* what is in fact the single, *synthetic* act through which the I posits for itself both itself and its world, thereby becoming aware in a single moment of both its freedom and its limitations, its infinity and its finitude. The result of such an analysis is the recognition that, although "the I simply posits itself," its freedom is never "absolute" or "unlimited"; instead, freedom proves to be conceivable -- and hence the I itself proves to be possible -- only as limited and finite. Despite widespread misunderstanding of this point, the *Wissenschaftslehre* is not a theory of the absolute I. Instead, the conclusion of both the *Foundation of the Entire Wissenschaftslehre* and of the *Wissenschaftslehre nova methodo* is that the "absolute I" is a mere abstraction and that the only sort of I that can actually exist or act is a *finite, empirical, embodied, individual self*.

The I must posit itself in order to be an I at all; but it can posit itself only insofar as it posits itself as limited (and hence divided against itself, inasmuch as it also posits itself as unlimited or "absolute"). Moreover, it cannot even posit for itself its own limitations, in the sense of producing or creating these limits. The finite I (the intellect) cannot be the ground of its own passivity. Instead, according to Fichte's analysis, if the I is to posit itself at all, it must simply *discover* itself to be limited, a discovery that Fichte characterizes as a ‘check’ or *Anstoß* to the free, practical activity of the I. Such an original limitation of the I is, however, a limit for the I only insofar as the I posits it as such. I does this, according to Fichte's analysis, by positing its own limitation, first, as a mere "feeling," then as a "sensation," then as an "intuition" of a thing, and finally as a "concept." The *Anstoß* thus provides the essential occasion or impetus that first sets in motion the entire complex train of activities that finally result in our conscious experience both of ourselves as empirical individuals and of a world of spatio-temporal material objects.

Though this doctrine of the *Anstoß* may seem to play a role in Fichte's philosophy not unlike that which has sometimes been assigned to the thing in itself in the Kantian system, the fundamental difference is this: the *Anstoß* is not something foreign to the I. Instead, it denotes the I's original encounter with its own finitude. Rather than claim that the Not-I is the cause or ground of the *Anstoß*, Fichte argues that the former is posited by the I precisely in order to "explain" to itself the latter, that is, in order to become conscious of the same. Though the *Wissenschaftslehre* demonstrates that such an *Anstoß* must occur if self-consciousness is to be actual, transcendental philosophy itself is quite unable to deduce or to explain the actual occurrence of such an *Anstoß* -- except as a condition for the possibility of consciousness. Accordingly, there are strict limits to what can be expected from any a priori deduction of experience. According to Fichte, transcendental philosophy can explain, for example, why the world has a spatio-

temporal character and a causal structure, but it can never explain why objects have the particular sensible properties they happen to have or why I am this determinate individual rather than another. This is something that the I simply has to discover at the same time that it discovers its own freedom, and indeed, as a condition for the latter. (It must be admitted, however, that Fichte's own ambitious descriptions of his project sometimes obscure the essential limits of the same and that he sometimes gives his readers the false impression that the *Wissenschaftslehre* proposes to provide a complete a priori deduction of all the empirical details of experience. This however is certainly not the case.)

Despite this important stricture on the scope of transcendental philosophy, there remains much that can be demonstrated within the foundational portion of the *Wissenschaftslehre*. For example, it can be show that the I could not become conscious of its own limits in the manner required for the possibility of any self-consciousness unless it also possessed an original and spontaneous ability to synthesize the finite and the infinite. In this sense, the *Wissenschaftslehre* deduces the power of productive imagination as an original power of the mind. Similarly, it can be shown that the I could not be "checked" in the manner required for the possibility of consciousness unless it possessed, in addition to its original "theoretical" power of productive imaginative, an equally original "practical" power of sheer willing, which, once "checked," is immediately converted into a capacity for endless striving. The foundational portion of the *Wissenschaftslehre* thus also includes a deduction of the categorical imperative (albeit in a particularly abstract and morally empty form) and of the practical power of the I. For Fichte, therefore, "the primacy of the practical" means not simply that philosophy must recognize a certain autonomous sphere within which practical reason is efficacious and practical considerations are appropriate; instead, it implies something much stronger: namely, the recognition that, as Fichte puts it, "the practical power is the innermost root of the I" and thus that "our freedom itself is a theoretical determining principle of our world." The *Wissenschaftslehre* as a whole can therefore be described as a massive effort to demonstrate that reason could not be theoretical if it were not also practical -- at the same time, to be sure, that also demonstrates that reason could not be practical if were not also theoretical.

Freedom, according to Fichte's argument, is possible and actual only within the context of limitation and necessity, and thus it is never "absolute," but always limited and finite. On the other hand, just as surely as a free subject must posit its freedom "absolutely" -- that is to say, ‘purely and simply’ (*schlechthin*) and "for no reason" whatsoever -- so must it never identify itself with any determinate or limited state of its own being. On the contrary, a finite free self must constantly strive to transform both the natural and the human worlds in accordance with its own freely-posited goals. The sheer unity of the self, which was posited as the starting point of the *Foundations*, is thereby transformed into an *idea* of reason in the Kantian sense: the actual I is always finite and divided against itself, and hence it is always striving for a sheer self-determinacy that it never achieves. Between the original abstraction of pure selfhood as sheer *Tathandlung* and the concluding (necessary) idea of a self that is only what it determines itself to be, in which "is" and "ought" wholly coincide, lies the entire realm of actual consciousness and real human experience.

4.2 Philosophy of Nature

Having established the foundation of his new system, Fichte then turned to the task of constructing upon this foundation a fully-articulated transcendental system, the overall structure of which is most clearly outlined in the concluding section of the transcripts of his lectures on *Wissenschaftslehre nova methodo*. According to this plan, which has no analog in Fichte's later writings, the *Entire Wissenschaftslehre* is to consisting of four, systematically interrelated parts:: (1) first philosophy, which corresponds to the "foundational" portion of the system, as presented in the *Foundation of the entire Wissenschaftslehre* and revised in the lectures on *Wissenschaftslehre nova methodo*; (2)"theoretical philosophy" or "philosophy of nature," (3) "practical philosophy" or ethics (corresponding to the content of the *System of Ethics*); and (4) "philosophy of the postulates," which includes the subdisciplines of "natural law" or "theory of right" (as expounded in the *Foundation of Natural Right*) and philosophy of religion.

By "philosophy of nature," Fichte seems to have had in mind something similar to Kant's *Metaphysical First Principles of Nature*, though Fichte himself devoted very little attention to the execution of such a project. The closest he ever came to developing a philosophy of nature according to transcendental principles is the compressed account of space, time, and matter presented in the *Outline of the Distinctive Character of the Wissenschaftslehre with Respect to the Theoretical Faculty* and the lectures on *Wissenschaftslehre nova methodo*. In neither of these works, however, does he make any effort to distinguish rigorously between the "theoretical" aspect of the foundational portion of his system and a distinctively "theoretical" subdivision of the same ("philosophy of nature"). In fact, a "philosophy of nature in accordance with the principles of the *Wissenschaftslehre*" turns out to me even more modest than Kant's and more closely resembles what later came to be called the philosophy of (natural) science than it does the speculative *Naturphilosophie* of Schelling and Hegel. Indeed, disagreement concerning the compatibility of a rigorously transcendental philosophy with a speculative, a priori "philosophy of nature" was the very issue that precipitated the rift between Fichte and his erstwhile disciple, Schelling. The popular picture of Fichte's attitude toward nature, namely, that he viewed the latter almost entirely from the perspective of human projects, that is, as the necessary realm for moral striving, is therefore very close to the truth.

4.3 Ethics

In contrast to Fichte's rather cursory treatment of purely theoretical philosophy, ethics or "practical philosophy," which analyzes the determinate ways in which willing and acting are determinable by principles of pure reason, constitutes a major portion of the Jena system, and the *System of Ethics* is Fichte's longest single book. Whereas theoretical philosophy explains how the world necessarily *is*, practical philosophy explains how the world *ought* to be, which is to say, how it ought to be *altered* by rational beings. Ethics thus considers the object of consciousness not as something given or even as something constructed by necessary laws of consciousness, but rather as something to be produced by a freely acting subject, consciously striving to establish and to accomplish its own goals and guided only by its *own* self-legislated laws. The specific task of Fichte's ethics is therefore, first of all, to deduce the categorical imperative (in its distinctively moral sense) from the general obligation to determine oneself freely, and, second, to deduce from this the particular obligations that apply to every free and finite rational being.

Like all of Fichte's systematic treatises of the Jena period, *The System of Ethics* begins with a detailed analysis of what is involved in the self-positing of the I. In this case, the focus is upon the necessity that the I posit for itself its own activity or "*efficacy*," and upon a detailed analysis of the conditions for doing this. In this manner Fichte deduces what he calls "the principle of all practical philosophy," viz., that something objective (a being) follows from something subjective (a concept), and hence that the I must ascribe to itself a power of free purposiveness or causality in the sensible world. The I must posit itself as an *embodied will*, and only as such does it "discover" itself at all. From this starting point Fichte then proceeds to a deduction of the principle of morality: namely, that I must think of my freedom as standing under a certain necessary *law* or *categorical imperative*, which Fichte calls "the law of self-sufficiency" or "autonomy," and that I *ought* always to determine my freedom in accordance with this law. This, therefore, is the task of the philosophical science of "ethics," as understood by Fichte: to provide an a priori deduction of our moral nature in general and of our specific duties as human beings.

Viewed from the perspective of practical philosophy, the world really is nothing more than what Fichte once described as "the material of our duty made sensible," which is precisely the viewpoint adopted by the morally engaged, practically striving subject. On the other hand, this is not the only way the world can be viewed, and, more specifically, it is not the only way in which it is construed by transcendental philosophy. For this reason it is somewhat misleading to characterized the *Wissenschaftslehre* as a whole as a system of "ethical idealism." As noted above, Fichte certainly does succeed in constructing an account of consciousness that fully integrates the imperatives and activities of practical reason into the very structure of the latter, but this integration is always balanced by a recognition of the constitutive role of theoretical reason and of the sheer, contingent "giveness" of the I's original determinacy (doctrine of the *Anstoß*).

4.4 Philosophy of Law (*Recht*)

The final portion of the Jena system is devoted to "the philosophy of the postulates," a discipline that Fichte conceived of as occupying the middle ground between purely theoretical and purely practical philosophy. In this portion of the system the world is considered neither as it simply is nor as it simply ought to be; instead, the moral world is itself considered from the perspective of the natural world (that is, one considers the postulates that theoretical reason addresses to the practical realm) or else, alternatively, the natural world is considered from the perspective of the moral law (that is, one considers the postulates that practical reason addresses to the realm of theory). The first of these perspectives is that of juridical philosophy or philosophy of law, or what Fichte calls the "doctrine of right" (*Rechtslehre*); the latter is that of the philosophy of religion.

Fichte's philosophy of right (or of "natural law"), as expounded in his *Foundation of Natural Right*, is one of the most original and influential portions of the Jena *Wissenschaftslehre*. Written prior to Kant's treatment of the same topic (in Part One of the *Metaphysics of* Morals), Fichte's philosophy of right is notable, first of all, because of the way in which it distinguishes sharply between the realm of ethics and that of "right" and tries to develop a complete theory of the latter (a "theory of justice") without appealing to the categorical imperative or the moral law, and secondly, because of the inclusion within this theory

of a thoroughly original "deduction" of the social character of human beings.

Fichte's transcendental account of natural right proceeds from the general principle that the I must posit itself as an *individual* in order to posit itself at all, and that in order to posit itself as an individual it must recognize itself as "summoned" or "solicited" by *another* free individual -- summoned, that is, to limit its own freedom out of respect for that of the freedom of the other. The same condition applies, of course, to the other; hence, mutual recognition of rational individuals turns out to be condition necessary for the possibility of I-hood in general. This a priori deduction of intersubjectivity is so central to the conception of selfhood developed in the Jena *Wissenschaftslehre* that Fichte, in his lectures on *Wissenschaftslehre nova methodo*, incorporated it into his revised presentation of the very foundations of his system, where the "summons" takes its place alongside "original feeling" (which takes the place of the earlier "check") as both a *limit* upon the absolute freedom of the I and a condition for the positing of the same.

The specific task of Fichte's theory of right is to consider the specific ways in which the freedom of each individual must be restricted in order that several individuals can live together with the maximum amount of mutual freedom, and it derives its a priori concepts of the laws of social interaction entirely from the sheer concept of an individual I, as conditions for the possibility of the latter. Fichte's concept of right therefore obtains its binding force not from the ethical law, but rather from the general laws of thinking and from enlightened self-interest, and the force of such considerations is hypothetical rather than categorical. The theory of right examines how the freedom of each individual must be externally limited <u>if</u> a free society of free and equal individuals is to be possible.

Unlike Kant, Fichte does not treat political philosophy merely as a subdivision of moral theory. On the contrary, it is an independent philosophical discipline with a topic and a priori principles of its own. Whereas ethics analyzes the concept of what is *demanded* of a freely willing subject, the theory of right describes what such a subject is *permitted* to do (as well as what he can rightfully be *coerced* to do). Whereas ethics is concerned with the inner world of conscience, the theory of right is concerned only with the external, public realm, though only insofar as the latter can be viewed as an embodiment of freedom.

Having established the general, albeit hypothetical concept of right, Fichte then turns to an investigation of the conditions necessary for the realization or "application" of the same: that is, for the actual coexistence of free individuals, or the existence of a free society. The sum of these "conditions" constitute the sum of our "natural rights" as human beings, rights that can be instantiated and guaranteed only within a deliberately constructed free society. On purely a priori grounds, therefore, Fichte purports to be able to determine the general requirements of such a community and the sole justification for legitimate political coercion and obligation.

The precise relationship of Fichte's theory of right to the social contract tradition is complex, but the general outline is as follows: Fichte presents an a priori argument for the fundamentally *social* character of human beings, an argument grounded upon an analysis of the very structure of self-consciousness and the requirements for self-posting. Only after this "deduction" of the concept of right and of the applicability of the same does he explicitly introduce the notion of what he calls the *Staatsbürgervertrag*

or "citizens' contract," a notion that he goes on to analyze into a series of distinguishable moments, including the "civil contract" proper (or "property contract"), the "protection contract," and the "contract of unification," all of which must be supplemented by the contracts of "subjection" and "expiation." Fichte thus propounds what one might call a "contract theory of the state," but not of human community.

As numerous commentators, beginning with Hegel, whose own *Philosophy of Right* was strongly influenced, both positively and negatively, by Fichte's *Foundations of Natural Right*, have pointed out, the actual theory of the state that Fichte himself, in Part Two of that work, erected upon what would appear to be a rather "liberal" theoretical foundation contains many elements that are not usually associated with the individualistic, liberal tradition -- including a general indifference to questions of constitutional structure, public participation in government, etc., and a strong emphasis upon the "police" functions of the state (functions which, for Fichte, were not limited to concerns of security, but also included those of social welfare). This, however, is not particularly surprising, since the function of the state in Fichte's system is primarily to employ coercion to guarantee that the parties to the contract will, in fact, do what they have promised to do and to insure that every citizen will have an opportunity to realize his own (limited) freedom. One of the more remarkable features of Fichte's conception of right is that every citizen is entitled to the full and productive employment of his labor, and hence that the state has a duty to manage the economy accordingly. The truth is that Fichte's social and political theory is very difficulty to fit into the usual categories, but combines certain elements usually associated with liberal individualism with others more commonly associated with communitarian statism.

4.5 Philosophy of Religion

In addition to the postulates addressed by theoretical to practical reason, there are also those addressed by practical reason to nature itself. The latter is the domain of the transcendental philosophy of religion, which is concerned solely with the question of the extent to which the realm of nature can be said to accommodate itself to the aims of morality. The questions dealt with within such a philosophy of religion are those concerning the nature, limits, and legitimacy of our belief in divine providence. The philosophy of religion, as conceived by Fichte, his nothing to do with the historical claims of revealed religion or with particular religious traditions and practices. Indeed, this is precisely the distinction between philosophy of religion and "theology."

As noted above, Fichte never had a chance to develop this final subdivision of his Jena system, beyond the tentative foray into this domain represented by his controversial essay "Concerning the Basis of Our Belief in a Divine Governance of the World" and the works he contributed to the ensuing "atheism controversy." In "Concerning the Basis of our Belief" he certainly seems to contend that, so far as philosophy is concerned, the realm of the divine is that of this world, albeit viewed in terms of the requirements of the moral law, in which case it is transformed from the natural to the "the moral world order," and that no further inference to a transcendent "moral lawgiver" is theoretically or practically required or warranted. In this same essay Fichte also sought to draw a sharp distinction between religion and philosophy (a distinction parallel to the crucial distinction between the "ordinary" and "transcendental" standpoints) and to defend philosophy's right to postulate, on purely a priori grounds,

something like a "moral world order." Philosophy of religion thus includes a deduction of the postulate that our moral actions really do make some difference in the world. But this is about as far as it can go.

With respect to the existence of God, the argument of Fichte's essay is primarily negative, inasmuch as it explicitly denies that any postulate of the existence of a God independent of the moral law is justifiable on philosophical grounds. In the wake of the atheism controversy, Fichte returned to this subject and, in his "From a Private Letter" and in Part Three of *The Vocation of Man*, attempted to restate his position in a manner that at least appeared to be more compatible with the claims of theism.

5. The later *Wissenschaftslehre* and the Reception of Fichte's Philosophy

For much of the nineteenth century, beginning with Hegel's self-serving interpretation of the history of modern philosophy, Fichte's *Wissenschaftslehre* was generally assimilated into the larger history of Germany idealism. Criticized by both Schelling and Hegel as a one-sided, "subjective" idealism and a prime instance of the "philosophy of reflection," Fichte's *Wissenschaftslehre* was almost universally treated as a superceded rung on the ladder "from Kant to Hegel" and thus assigned a purely historical significance. Neglected as the *Wissenschaftslehre* may have been during this period, Fichte was not entirely forgotten, but remained influential as the author of the *Addresses to the German Nation* and was alternately hailed and vilified as one of the founders of modern pan-German nationalism.

This same situation prevailed throughout much of the twentieth century as well, during which Fichte's fortune seemed closely tied to that of Germany. Particularly during the long periods preceding, during, and following the two World Wars, Fichte was discussed almost exclusively in the context of German politics and national identity, and his technical philosophy tended to be dismissed as a monstrous or comical speculative aberration of no relevance whatsoever to contemporary philosophy. There were, to be sure, isolated exceptions and authors such as Fritz Medicus, Martial Gueroult, Xavier Léon, and Max Wundt who, during the first half of the twentieth century, took Fichte seriously as a philosopher and made lasting contributions to the study of his thought. But the real boom in Fichte studies has come only in the past four decades, during which the *Wissenschaftslehre* has once again become the object of intense philosophical scrutiny and lively, world-wide discussion -- as is evidenced by the establishment of large and active professional societies devoted to Fichte in Europe, Japan, and North America.

J. H. Stirling once quipped that "Fichte had *two* philosophical epochs; and if both belong to biography, only one belongs to history," and until quite recently there was a great deal of truth to this observation. Indeed, even today, Fichte's technical writings of the post-Jena period remain little-known to the vast majority of philosophers. Admittedly, it is hard to recognize these late texts -- which drop the strategy of beginning with an analysis of the self, along with the strong emphasis upon the "primacy of the practical," and which include unembarrassed references to "the absolute" and even to "absolute being" -- as the work of the same author who wrote the *Foundations of the Entire Wissenschaftslehre*. Though Fichte himself always insisted that his basic philosophy remained the same, no matter how much his

presentation thereof may have altered over the years, many sympathetic readers and not a few well-informed scholars have found it impossible to reconcile this claim with what at least appear to be the profound systematic and doctrinal differences between the "early" and "late" *Wissenschaftslehre*. It is therefore not surprising that the problematic "unity" of Fichte's thought continues to be vigorously debated by experts in the field.

Whatever one may conclude concerning the relationship between Fichte's earlier and later writings, it is certainly the case that, with the publication of numerous, faithfully edited "new" manuscripts of later versions of the *Wissenschaftslehre*, the focus of much of the best contemporary Fichte scholarship has shifted to his later texts, most of which were entirely unknown to earlier generations of readers. Seldom has a new edition of a philosopher's literary corpus had a greater effect upon the contemporary reputation of the thinker in question or a more stimulating effect upon contemporary scholarship than in the case of the monumental new critical edition of Fichte's works begun in the early nineteen-sixties under the auspices of the Bavarian Academy of the Sciences and the general editorship of Reinhard Lauth and others. Now nearing completion, this edition has contributed directly and enormously to the contemporary revival of interest in Fichte's philosophy in general, and in the later versions of the *Wissenschaftslehre* in particular. Much of the best recent work on Fichte, particularly in Germany, Italy, and Japan, has been devoted exclusively to his later thought. Stirling's observation is thus no longer true, inasmuch as the work of Fichte's "second epoch" has, however belatedly, now become the object of genuine and lively philosophical discussion and dispute.

In contrast, anglophone Fichte scholarship, which has also experienced quite a renaissance of its own over the past few decades, has remained largely focused upon the "classical" texts of the Jena period. This is no doubt due, in large part at least, to the appearance, during these same decades, of new, reliable translations of almost all of Fichte's early writings and the lack of translations of his later, unpublished texts. But it is also a reflection of the relatively anemic tradition of Fichte scholarship in England and North America, where even the early *Wissenschaftslehre* has long been neglected and underappreciated. Until quite recently, virtually no scholars writing in English were interested in examining the *Wissenschaftslehre* in its own right, but were mainly concerned to determine Fichte's position in relationship to Kant's or Hegel's. This situation, however, has fundamentally altered, and some of the most insightful and original current work on Fichte is being done in English.

Bibliography

Editions of Fichte's Complete Works in German

- *Johann Gottlieb Fichtes nachgelassene Werke*, 3 vols., ed. I. H. Fichte (Bonn: Adolph-Marcus, 1834-35).
- *Johann Gottlieb Fichtes sämmtliche Werke*, 8 vols., ed. I. H. Fichte (Berlin: Veit, 1845-46). [Taken together, these 11 volumes, edited by Fichte's son, constituted the first attempt at a complete edition of his works and are still widely cited and reprinted, most recently by de Gruyter, under the title *Fichtes Werke*.]

- *J. G. Fichte: Gesamtausgabe der Bayerischen Akademie der Wissenschaften*, ed. Reinhard Lauth, Hans Jacobs, Hans Gliwitzky, and Erich Fuchs (Stuttgart-Bad Cannstatt: Frommann, 1964 --) 32 vols to date. [Organized into four separate series -- writings published by Fichte, unpublished writings, correspondence, and student lecture transcripts -- this monumental critical edition, which should be complete by 2010, supersedes all earlier editions.]

Individual Works and English translations

- *Versuch einer Kritik aller Offenbarung* (1792; 2nd ed., 1793). *Attempt at a Critique of All Revelation*, trans. Garrett Green (New York: Cambridge University Press, 1978).

Salomon Maimon

Salomon Maimon (1753-1800), the man whom Kant described as the best of his critics, stands as one of the most acute and complicated thinkers -- and certainly one of the most fascinating personalities -- of the 1780s and 1790s. By granting the principle of sufficient reason unlimited validity Maimon embraces a radical form of rationalism. By presenting strong criteria for the validity of knowledge Maimon suggests that even Kant's attempt to limit epistemological claims to the realm of possible experience cannot be secured without a substantial ontological commitment. By doing this Maimon tries to present Kant with the dilemma of either adopting elements from the dogmatic metaphysics Kant set to challenge, or having his system undermined by skepticism. In revealing what he sees as the skeptical implications of rationalism, Maimon raises important objections to Kant's critical idealism, as well as develops deep insights into the problems of experience and givenness. His ‘skeptically rationalist’ claims about the nature and limits of human cognition present a distinctive perspective on the Kantian project of transcendental idealism, as well as on central epistemological issues concerning the relation between thought and the world.

1. Intellectual Biography

“*Scholars of Wisdom have no rest in this world or in the world to come*.”

This Talmudic saying, with which Maimon concludes his first philosophical work, applies strikingly well to the life story of Salomon Maimon. Maimon was born in 1753 in Suchowyborg, a village next to the town of Mir in Lithuania. His family, which originally was rather wealthy, fell into poverty due to poor management of its properties. Thus, Maimon's father became a children's teacher, an example that was followed later by his son Salomon. Maimon received a traditional religious education, which concentrated mainly on the study of the *Talmud*. At the age of 11, shortly after the death of his mother and following a comedy of errors involving the mothers of two young girls, Maimon was married in an arranged ceremony, and three years later his first son, David, was born. During his early adulthood, Maimon developed a keen curiosity about the sciences and philosophy. The most crucial influence was that of Maimonides' *Guide of the Perplexed*, through which Maimon became acquainted with Aristotelian philosophy in its medieval cloth. Maimon's attachment to Maimonides -- both personally and philosophically -- ran throughout his life. Even Maimon's own name was adopted as an expression of respect towards this teacher (At the time, few Jews adopted family names. Before taking the surname ‘Maimon’, Maimon used to be called after his father: Salomon *ben* ("*son of*") *Joshua*). Maimon also developed an interest in Kabbalistic texts, which in spite of his relatively young age, he attempted to study and interpret according to the bodies of knowledge he had already acquired (i.e., Maimonidean philosophy). In his early twenties Maimon went to visit the *Maggid* of Mezrich, the contemporary leader and one of the founders of *Hassidism*. Though in his *Lebensgeschichte* Maimon passes a strong negative judgment against the *Hassidic* movement, it seems that several main themes of his later philosophy developed through a careful dialogue with its teachings. In his mid-twenties, hoping to widen his knowledge of philosophy and the sciences, Maimon left his family and went to Berlin (under the pretense of attempting to study medicine there). This first visit to Berlin ended shortly and grimly. Having confided to one of the officers of the Jewish community that the purpose of his visit was to study philosophy and that he intended to publish a new commentary on Maimonides' *Guide of the Perplexed*, Maimon was asked to pack his belongings and leave the shelter of the Jewish community -- and thus the city -- at once. The following half year Maimon spent as a wandering beggar, till he reached Posen, where he was offered a shelter and a position as a tutor at the house of one of the city's Jews. During his stay in Posen Maimon wrote one of his most fascinating works, *Hesheq Shelomo* (“Solomon's Desire.” See the Bibliography). In 1780 Maimon went again to Berlin. This journey was much more successful and Maimon established a close connection with Moses Mendelssohn and entered the circles of the *Haskala* (the Jewish Enlightenment movement) in Berlin. Yet neither Berlin nor its enlightened Jews provided a real home for Maimon. For the cultured Jews of Berlin, Maimon was a rude *Ostjude* (East-European Jew), who spoke awful German accompanied by a variety of wild gesticulations. They did, however, acknowledge the genius of this person, who could, for example, read a difficult book of mathematics for the first time, and then explain it -- in his savage manner -- a short while later. Similarly, Maimon had little appreciation for these fine bourgeoises who, free from any barriers which would impede their ability to study the sciences, only contented themselves with a shallow acquaintance with what a civilized person *should* know. Furthermore, they lacked the sharpness of mind of his fellow Talmudists in Poland. Maimon does seem to have had a genuine appreciation for Mendelssohn, both because of his kindheartedness and because, unlike most others of the circles of the Jewish Enlightenment, Mendelssohn had a reasonable grasp of the *Talmud* and rabbinic literature.

In 1783, after a journey to Hamburg, Amsterdam and then back to Hamburg, Maimon entered a

gymnasium in Altona, where he stayed for two years. During this period Maimon studied several European languages and improved his knowledge of the natural sciences and his command of German. In 1785, Maimon left Altona for Berlin, where he met Mendelssohn for the last time. Later that year Maimon moved to Dessau, where he wrote a Hebrew textbook on mathematics, and subsequently settled in Breslau. Here, after a failed attempt to study medicine, Maimon again took up the position of a tutor. While staying in Breslau, Maimon translated Mendelssohn's *Morgenstunden* into Hebrew and wrote a Hebrew textbook on Newtonian physics -- *Ta'alumoth Hochma* (“*Mysteries of Wisdom*”). After more than a decade of separation, Maimon's wife, accompanied by their eldest son, succeeded in locating him in Breslau, and demanded that he either return to Lithuania or get a divorce. Reluctant to sever his ties with his past, Maimon tried to postpone the decision, but after his wife insisted that he must make the choice, he finally agreed to the divorce.

Towards the end of the 1780s Maimon traveled again to Berlin. There he heard about Kant's new philosophy, and for a couple of months dedicated himself to a careful study of the *Critique of Pure Reason*. In his *Autobiography*, Maimon alludes to his “rather curious” methods for understanding this text:

> In the first reading I reached a vague sense of each section, which through subsequent readings I then sought to make determinate, and by this to penetrate the meaning of the author. This is what is properly meant when one thinks oneself into a system. Since I had already used this method in mastering the systems of Spinoza, D. Hume, and Leibniz, it was natural that I would be led to think of them as a ‘Coalition-System.’ This I actually discovered, and by and by set it out in the form of notes and observations on the *Critique of Pure Reason*(GW I, 557 | LB 253).

Maimon put his thoughts about the *Critique* in a letter he sent to Kant through a common friend, Markus Herz. Kant responded in a letter full of praise for Maimon, describing him as “having an acumen for such deep investigation that very few men have” and claiming that “none of my critics understood me and the main questions as well as Herr Maimon does.” (Ak. 11:48)

Kant's recognition opened for Maimon the salons of Berlin as well as the contemporary leading journals, in which Maimon started publishing. The story of the crude genius who came from the East and penetrated the heart of German philosophy became a common topic of small talk in these circles. In 1790, Maimon published an expanded version of his comments of Kant's first *Critique* as the *Versuch über die Transcendentalphilosophie* (“An Essay on Transcendental Philosophy”). A year later, Maimon collaborated with the members of the Jewish Enlightenment and prepared a Hebrew commentary on Maimonides' *Guide of the Perplexed.* (The publisher decided to publish only the first part of this work, since he found Maimon's commentary much too deep philosophically, and thus unfitting for the political purposes of propagating the ideas of the enlightenment among the Jews.)

During the early 1790s, Maimon struck a close friendship with Karl Philipp Moritz (the author of *Anton Reiser*). Maimon became a frequent contributor and later the co-editor of Moritz's *Magazin zur Erfahrungsseelenkunde*, which was in fact the first journal dedicated to the study of psychology.

Following Moritz's death in 1793 Maimon attempted to find a new patron. He established a connection with Goethe, who invited him to Weimar, yet because of reasons that remain unclear, this relationship did not succeed. Maimon's material life in that period was quite miserable. He lived in extreme poverty, and spent the little money he earned on alcohol -- for the price of a drink one could buy his conversation in a tavern. In 1795, Maimon accepted a generous offer by a young Silesian nobleman, Graf Kalkreuth, and moved to the latter's estate in Siegersdorf (currently: Kozuchow) in Lower Silesia. From this time until his death in November 22, 1800, Maimon led a quiet, though lonely and melancholic, life on Kalkreuth's estate. In May 1800, Maimon wrote to one of his Jewish friends in Berlin, attempting to arrange his return to Berlin -- and to find financial support for that purpose -- but this plan never materialized.

In the last decade of his life, Maimon wrote ten books, and numerous articles. The most important among these books (apart from the *Transcendentalphilosophie*) are his philosophical works, *Versuch einer neuen Logik, oder Theorie des Denkens (An Attempt at a New Logic, or a Theory of Thinking*) (1793), *Kritische Untersuchungen über den menschlichen Geist, oder das höhere Erkentniß und Willensvermögen* (*Critical Investigations on the Human Mind, or the Highest Faculty of Knowledge and Will*) (1797), and his *Lebensgeschichte* (*Autobiography*) (1792/3), which is his only work which achieved public recognition and popularity.

2. Maimon's Critique of Kant

In the highly polarized German philosophical community in the 1790s, Maimon's intellectual allegiances remained rather ambiguous. In a letter of 1791, Maimon had written to Kant that while he found the skeptical part of the *Critique of Pure Reason* wholly convincing, he harbored doubts about the more dogmatic aspects of Kant's system. Kant, of course, viewed Maimon not as an ally, but as the best of his critics -- it remains an open question whether Maimon saw himself as fundamentally a friend or foe of the critical philosophy. At the very least, however, Maimon's criticisms of the *Critique* cut to the core of Kant's transcendental idealism, in particular because they engage with what Maimon sees as an *internal* problem for Kant's system.

Perhaps the most obvious problem -- and certainly one of the earliest -- that Kant faces concerns the issue of the thing in itself. In order to account for the content of cognition, Kant notoriously posits a thing in itself that stands outside of the realm of possible experience yet nevertheless serves as the causal source of cognitive content. This mysterious entity was attacked most famously by Jacobi, with his accusation that one could not enter into Kant's system without the assumption of the thing in itself, but that with such an assumption one could not remain within it. Maimon too was quick to point out that the thing in itself could not be understood realistically. Rather, Maimon argues, the thing in itself must be understood as completely conceptual determination of an object, which can be approached only asymptotically. Against Kant's claims about a noumenal realm of things as they are in themselves, Maimon holds that the thing in itself stands only as an object of inquiry, rather than an independent, noumenal entity. As such, while Maimon agrees with Kant that since we are finite beings the thing in itself is in fact beyond the realm of possible experience, this does not imply that the thing in itself cannot *in principle* be an object of cognition.

Maimon's criticisms of Kant's account of the thing in itself, however, are connected to a deeper concern about the notions of experience and cognition that stand at the heart of Kant's critical idealism. Kant posits the thing in itself in large part because of his commitment to a type of cognitive dualism, in which human experience is taken to involve both a faculty of thought (the understanding), as well as a faculty of receptivity (sensibility). In order to have any content, experience requires data, which must be given to the subject through the senses. Moreover, the data of experience cannot be produced by the faculty of thought itself. The given content of sensibility plays an ineliminable role in cognition, and its source must ultimately be traced to the subject's being affected by something distinct from itself, a role played by the thing in itself. But while the content of thought is provided by the affection of an object on the faculty of sensibility, the way in which this content is cognized remains the purview of the faculty of the understanding. Mere affection, in other words, is not equivalent to cognition. In Kant's terms, the “understanding is not capable of intuiting anything, and the senses are not capable of thinking anything.” (A52/B56)

For Maimon, Kant's cognitive dualism -- which begins with wholly distinct faculties of cognition -- fails to explain how the various elements can come together in a way that makes experience possible. On this objection, Kant cannot justify his assumption that concepts and intuitions necessarily unite in cognition. In more Kantian terms, Maimon calls into question Kant's answers to both the *quid facti* and the *quid juris* that begin the Transcendental Deduction in the first *Critique*. According to Maimon, while the *quid facti* -- the question of the fact of our use of a priori concepts in experience -- is taken by Kant to be an unproblematic statement about the nature of human experience, the very assumption that we in fact do possess the type of experience Kant ascribes to us can be called into doubt. Kant's central argument in the Transcendental Deduction begins by assuming that experience exhibits a ‘dualistic’ structure, but according to Maimon, this position is not warranted, since the presumed constituent elements of experience (bare intuitions or concepts) are never themselves objects of experience. For Maimon, Kant's transcendental arguments remain mere ‘castles in the air’: while they might be valid, they fail to provide the ‘fact of experience’ that would make them sound. From the beginning, then, Maimon views Kant's transcendental project with suspicion.

This suspicion becomes an explicit problem, Maimon claims, when the specific structure of Kant's system is examined. Here, Maimon argues, the *quid juris* of the deduction -- the question about the legitimate use of the categories -- can likewise be cast into doubt. While Kant claims in the Deduction that the *a priori* concepts of the understanding -- the categories -- are necessary conditions on the unity of the manifold of sensible data given in intuition, Maimon argues that such a position leads to serious problems for the later claims Kant makes in the ‘Schematism’ and ‘Principles’ sections of the Critique. According to Maimon, Kant cannot explain how different categories are able to discriminate between different intutive content. Using the example of causality, Maimon argues that Kant has no way of explaining why some orders of perceptions represent causal connections, and why other orders of perceptions are merely associative. The reason for this claim is found in the fact that while Kant grounds the category of causality in a necessary order of perceptions, his justification for this claim appeals not to the content of the perceptions, but only to their formal ‘rule-governed’ connection -- but, as Maimon argues, *any* order of perceptions can meet this formal requirement. Yet since the content of intuitions

does not contain any temporal ordering, Kant explicitly bars an appeal to such content in applying the category of causality. As such, Kant's account of cognition faces a dilemma: either it must appeal to the content of experience and so violate Kant's own strictures, or the application of categories is merely arbitrary. Kant's central epistemological commitment -- his ‘cognitive dualism’ -- then leads, Maimon claims, to insuperable problems.

While Maimon's objections to Kant focus on specific issues that arise in the *Critique*, they all rest on Maimon's commitment to a type of ‘skeptical rationalism.’ Maimon notes that in the *Versuch über die Transcendentalphilosophie* the important problem of the *quid juris* was presented in a much wider sense than that in which Kant takes it, and thereby [such a position] allowed a place for Hume's skepticism in its complete power. On the other hand, the complete solution to this problem necessarily leads to Spinozistic or Leibnizian dogmatism (GW I, 558 | LB 254).

Moreover, in the face of the question of how the understanding can subsume or comprehend a given object, Maimon notes that “for the Kantian system, [which claims] that our sensibility and understanding are two entirely different sources of our cognition, this question is … unanswerable; on the other hand, for the Leibizian-Wolffian system, in which both [sensibility and understanding] flow from the same cognitive source (their difference consisting only in the grades of completeness of this cognition), the question can easily be answered.” (GW II, 63-4 | VT 63-4) But while Maimon sees in the dogmatism of Spinoza, Leibniz and Wolff a means of avoiding the problems that attend Kant's ‘cognitive dualism,’ he remains a skeptic about whether this solution can ever be demonstrated.

3. Content, Givenness, and Space and Time

The rejection of cognitive dualism raises a rather vexing problem for Maimon: if the content of cognition is not to be found in the affection of the merely passive faculty of sensibility, where does the content come from? On the face of it, of course, it seems clear that humans are not wholly responsible for the world of experience, but rather encounter it; Maimon must provide some explanation of the ‘given’ content of experience without appealing to something like the Kantian cognitive dualism he finds so problematic.

Although the details of Maimon's answer to this problem remain obscure, the kernel of his position can be found in his analysis of what it is to be a finite cognizer. While Kant moves from the fact of our human finitude to the need for a ‘given’ element of cognition, Maimon claims that such a step need not be taken. Instead of characterizing finitude in terms of the need for a passive faculty of receptivity, Maimon insists that finitude only implies incompleteness in our cognition -- but this incompleteness does not warrant any conclusions about the provenance of the matter of cognition. The content of sensibility is simply that which is passive in cognition -- namely, that upon which the understanding operates. The expression that content is given from ‘outside of us,’ Maimon writes, means only “something in a representation of which we are conscious of no spontaneity, that is, (in view of our consciousness) a mere passivity without activity.” And, he continues, the word ‘given’ signifies not “something in us that has its cause outside of us … rather, [the given] means merely a representation, whose manner of origin in us is

unknown to us.” (*GW* II, 203 | VT 203) What we take to be merely given to us in experience can in fact be explained in terms of a productive -- and hence active -- capacity of the mind, although the procedures of this activity remain unknown to us.

In this respect Maimon revives the Leibnizian notion that there is not a difference in kind, but only in degree, between a finite and an infinite intellect. Maimon argues that for an infinite intellect, all of the content of thought is consciously produced through the mind's own activity -- by virtue of its infinity, nothing needs to be given to such an intellect. By the same token, Maimon holds that we can think of finite cognizers in the same terms, but with the crucial difference that finite minds are not aware of the productive capacities that create the matter of experience. The supposedly given content provided by sensibility, in other words, can in fact be explained in terms of the ‘subconscious’ productive capacities of the active mind. In this respect, Maimon argues that our minds are limitations of the divine or infinite mind; our active powers are conscious, he claims, in mathematics, where we display a ‘god-like’ ability to create content according to rules of thought. In the case of empirical content, however, the creative process remains uncognized.

These ‘subconscious’ products become conscious to the finite mind, Maimon claims, by being represented in space and time. The contrast with Kant is again important, for while Kant claims that space and time are forms of human intuition, Maimon maintains that space and time are in fact the ways in which humans represent conceptual differences between thoughts. Space and time, that is, “are both concepts and intuitions, and the latter presupposes the former.” (GW II, 18 | VT 18) Space and time are concepts as representations of the differences of things in general, but they are intuitions when they represent a particular sensible object in relation to other sensible objects. As finite cognizers, we represent in space and time what we have not completely conceptualized. The fact that we represent content spatially and temporally indicates only that there is some incompleteness in our conception of the world, and not that this content is provided by a realm of wholly independent objects. Maimon claims that the representations of space and time as intuitions arise as the result of the faculty of imagination, which is, as he describes it, the faculty of fictions (GW III, 61 | PW 37). Space and time are then taken to be fictions in that they add properties to objects that are not present in the conceptual determination of these objects. As such, they serve as “negative criteria” for the incompleteness of our knowledge of objects (GW V, 192 | VnL 134). Although we never have complete determination, we do get *nearer* to the complete concept of an object. The fact that we represent objects in space and time points to the fact that something *remains to be* determined -- spatial or temporal diversities, that is, must have their ground in some conceptual differences. The representations of space and time provide indications that “the concepts of experience, and consequently also the determined relations of objects of experience, are incomplete.” (*GW* V, 192 | VnL 134)

This emphasis on the fictional nature of spatial and temporal properties again echoes the Leibnizian explanation of space and time as the representation of conceptual differences, but where Leibniz claims that space and time are derived from monadic relations, Maimon argues that the intuitions of space and time are in fact *a priori* human forms of representation, or, in Maimon's terms, ‘forms of difference’. In order to represent an object in space and time, Maimon maintains, the conceptual content that grounds such a representation must contain a diversity in order to be represented spatially and temporally. An

intuited visual field of homogeneous red, for example, would not be spatially represented, since there would not be any diversity present. Spatiality would arise only with the introduction of some distinct content -- a spot of green in the red field, for example.

For Maimon, the *formal* nature of space and time suffices to yield mathematical and geometric necessity. In mathematics, Maimon claims, space and time are *given a priori* to the faculty of cognition; the objects of mathematics are “nothing but space and time in all their possible modifications.” (*GW* V, 184 | VnL 126) Mathematics, that is, relates to an object given a priori, or rather “itself determines these objects *a priori*.” (*GW* V, 183 | VnL 125) The objects of mathematics and geometry are then directly created or determined according to the understanding's *a priori* rules of production. For Maimon, as for Kant, the ground of the a priority and necessity of geometry and arithmetic lies in the need for the construction and exhibition of concepts in intuition.

Space and time are then presented as *a priori* ‘forms of difference,’ but a question remains about the content of experience: the supposedly independent world of objects, in all of its variety and multiplicity, still needs to be explained. On this question, unfortunately, Maimon's position is particularly obscure. In the *Versuch über die Transcendentalphilosophie*, Maimon develops a theory about the content of experience in terms of what he calls ‘infinitesimals of perception.’ Here the invocation of the calculus is deliberate, for he argues that the content of experience can be explained in terms analogous to the way in which infinitesimals are treated in mathematics. A line, for example, can be understood as composed of an infinite number of points, each of which stands in relation to the others; moreover, these points are densely ordered, for there are an infinite number of points between any two points. But while the differences between the points of the line are themselves infinitely small, the relation between them is a determinate value -- the slope, which can be calculated for any point on the line. Likewise, Maimon claims, the content of experience can be understood as analogous to a ‘perceptible line’ that is composed of an infinite number of smaller components, none of which is ontologically distinct from the experience itself. On this view, “sensibility provides the differentials to a determined consciousness; the imagination produces from these [differentials] finite (determinate) objects of intuition; the understanding produces from the relations of these different differentials, which are its objects, the relation from which arise sensible objects.” (*GW* II, 31-2 | VT 31-2) In this sense, there is -- at least in principle -- no need to appeal to a content given from outside of experience; instead, experience is itself composed or ‘integrated’ from the posited infinitesimal elements of thought. As finite cognizers, we *represent* in space and time the purely conceptual differences that are simply presented in thought. (A similar strategy for dealing with the problem of the thing-in-itself was developed a century later by the Marburg Neo-Kantians, especially Hermann Cohen.)

While the theory of the infinitesimals of perception is complex, it points toward Maimon's deeper rationalism. Both his objections to Kant's account of cognition as well as his own positive project turn on a rejection of what might be called ‘brute givens.’ For Maimon, givenness stands in opposition to cognition, for he holds that no explanation can be provided for how merely given content can be taken up in thought -- how, that is, the active faculties of thought can legitimately apply to a passively received given. By attempting to explain givenness within a larger framework of an active consciousness, Maimon presents a position that avoids -- at least in principle -- the problems that Maimon sees with Kant's

cognitive dualism.

4. Logic and the Law of Determinability

In the *Critique of Pure Reason* Kant contemplates the possibility of a law that would govern the *content* of synthetic judgements. This law is supposed to be a complement to the principles of non-contradiction and excluded middle, which govern the logical *form* of both synthetic and analytic propositions. The law, which Kant terms “The Principle of Thoroughgoing Determinability” (*Grundsatz der durchgngigen Bestimmung*), states that “of every pair of possible [and opposite] predicates, one of them must apply” to every single thing [A573/B601]. As a result, every single thing would be thoroughly determined with regard to any pair of opposite predicates. This law seems to necessitate the idea of the sum total of all possibility, and as a further result, the concept of an *ens realismus*. Kant argues, however, that this derivation is not valid insofar as it attempts to apply a principle that is limited to possible experience to all things (including things in themselves) [A583/B661]. Like Kant, Maimon too suggests a transcendental principle that will govern synthetic propositions with regard to their content and not their form (which is governed by the law on non-contradiction). In spite of these similarities, Maimon's law the Law of Determinability (*Satz der Bestimmbarkeit*) is significantly different from the one offered by Kant. The two laws not only differ with regard to their contents, but they also serve different functions, and have different weight in the two systems. While the Kantian law has a relatively marginal place within his systems (and is considered by many scholars as a mere residue of the metaphysical inheritance of Baumgarten and Wolff), Maimon's law seems to be the crucial axis of his positive philosophy (and seems to be influenced by Spinozistic metaphysics). The laws also differ with regard to their domains of applicability. While Kant restricts his law to possible experience, Maimon argues that the demands of his law are satisfied only within the domain of *a priori* mathematical thinking, and that empirical cognition fails to pass its test.

The main aim of Maimon's Law of Determinability is to provide a *criterion* that would distinguish between syntheses that reflect a *real* connection between concepts, and *arbitrary* syntheses, which result from the activity of the imagination. Real syntheses are of crucial importance for Maimon, since through this kind of syntheses we can create new concepts, and, in the case of *a priori* syntheses, even create genuine objects. According to Maimon in any real synthesis of a subject and a predicate, the following two principles must be observed:

> (1) A principle for the *subject* in general: every subject must be a possible object of consciousness, not only as a subject but also in itself;
>
> (2) A principle for *predicates*: every predicate must be a possible object of consciousness, not in itself, but only as a predicate (in connection with the subject) What does not conform to this principle can be a merely *formal*, or *arbitrary*, but not a *real* thought (GW V, 78 | VnL 20).

A synthetic judgment then accords with the law of determinability when its predicate is a real

determination of the subject (i.e., when its predicate is asymmetrically dependent upon its subject). Thus, for example, in the synthesis straight line, the predicate straight is a real determination of the subject line, since one can think of the subject without the concept of the predicate, while one can conceive of straightness only through the concept of a line. In an empirical synthesis, such as, the red line, the predicate is merely an arbitrary determination insofar as our intellect does not decipher any internal connection and dependence between the subject and the predicate (GW II, 92-3 | VT 92-3). Another paradigmatic example, which Maimon uses to explain the notion of real synthesis, is that of a right angle. Here too, Maimon argues, the subject (angle) can be thought in itself without relation to the predicate, while the predicate (right) cannot be thought without the subject. The use of mathematical examples is not coincidental, since Maimon argues that it is only in mathematics that we can find real syntheses, namely, syntheses that pass the test of the law of determinability. This special advantage of mathematics is due to the role of construction in mathematics. Thus, in the case of the straight line the intellect commands a construction of a line in pure intuition according to the concept of straight. In such a way, the connection between the subject and the predicate, while synthetic, is nevertheless necessary. By contrast, a judgment such as The cup is green fails to accord with the law of determinability, for the connection between the subject and the predicate remains merely problematic. For our intellect, the greenness of the cup is something that is merely encountered, rather than consciously constructed, and thus it fails to express any internal connection between the subject and its predicate. By using the Law of Determinability Maimon thought to provide a way both to generate new concepts as well as to decipher the basic categories of thought. Mathematics provides us with an example of how should these derivations work. However, this law also seems to point out the unreliability of empirical judgments.

Determinability then provides a standard of synthetic judgments: it tells us not merely the form that such judgments must take, but also specifies what counts as a legitimate content of such a judgment. In this sense, determinability provides a certain cohesion between the products of the mind. But, while the Law of Determinability presents the standard which real thought must meet, it is important to note that Maimon remains dubious about the possibility of ever achieving real thought except in the realm of mathematics. Only when the determinable relation between the subject and predicate of a judgment is *constructed* can real thought be reached; in empirical judgments about the world, no such determinable relation can be proved. And it is just this concern that leads to Maimon's skepticism.

5. From Dogmatism to Skepticism (and Back?)

Maimon describes his position as “Humean dogmatism,” (or, alternately, as “Leibnizian skepticism”), and this characterization is apt. His commitment to both camps, however, makes the question of his ultimate allegiance a difficult one. While Maimon agrees with the rationalists about the standards provided by reason, he claims to follow Hume in denying that there can ever be a proof of the applicability of reason to the world of experience. In this respect, the status of the principle of determinability encapsulates Maimon's position: while we can comprehend what the standard of real thought involves (since we have an example in mathematics), we can never be sure about its application to empirical matters (since we cannot guarantee the requisite determinable relation between subject and predicate). Maimon's skepticism arises from the lack of the required ground for this use [of the

categories], namely, the insight into the relation of determinability (that the subject, as the determinable, can be an object of consciousness in itself, while the predicate cannot be so in itself, but only as a determination [of the subject]). The categories are therefore, according to me, determined not for empirical use, but only for the objects of mathematics determined *a priori* (*GW* V, 495-6 | VnL 437-8).

Maimon here exposes what seem to be the skeptical implications of his rationalism, for while the standards of real thought are available to us as finite cognizers, the satisfaction of these criteria remains beyond our power.

But while Maimon's skepticism commits him to the view that human knowledge remains incomplete, he does not abandon the notion of intellectual progress. While we can despair of ever reaching complete knowledge, the rationalist project at least holds out the hope of advancing us in our conceptual grasp of the world. In this sense, while Maimon is led by his skeptical conclusions to see human cognition as essentially antinomial, he retains the prospect of a solution:

> Thought in general consists in a relation of a form (a rule of the understanding) to matter (the given subsumed by [the form]). Without matter one cannot attain consciousness of the form, and consequently the matter is a necessary condition of thought; that is, for the real thought of a form or rule of the understanding, there must necessarily be given a matter to which this form relates. On the other hand, however, the completeness of the thought of an object requires that nothing be given in [this completeness], but rather that everything must be thought. Since we cannot deny either of these demands, we must therefore try to satisfy both, in that we make our thought ever more complete, whereby the matter always approaches the form, through infinity -- and this is the solution of this antinomy (*GW* III, 186-7 | PW 162-3).

This relation between skepticism and rationalism is nicely captured in a biblical metaphor Maimon offers:

> Reason, which in its theoretical employment is conditioned by given objects, and is thus very limited, is now, in its practical use in relation to the will, absolute. The principle which it presents is both determined in itself, and in its application is capable of no illegitimacy. This highly pleasant prospect is certainly doubted by the skeptic, who reduces any law, as an original fact, into many. An uplifting and at once humbling voice calls out to him: “You should see the promised land from afar, but you may not enter it!” [Deut 34:4] Still, fortunately the seeing and the entering are the same: for those who boast of being able to enter can, for their legitimation, do no more than show the distant view (*GW* VII, 554).

The vision of the promised land is an especially apt characterization of Maimon's skepticism: we can see what conditions would need to be satisfied for real cognition, but we are barred from ever knowing if these conditions are met. When pressed for a warrant for his claims to certainty, the dogmatist can do no more than simply point to the far-off land of philosophical milk and honey.

6. Ethics

Unlike Kant and most of the German Idealists, Maimon denies that practical reason enjoys a primacy over theoretical reason. For Maimon, the force of both morality and epistemology resides in the notion of universal validity: as rational beings we are bound by both philosophical truth and moral duty. As Maimon puts the matter, “the moral good is good only because it is true.” (*GW* II, 405 | VT 409) As such, the theoretical and the practical go hand in hand; for Maimon, it makes no sense to follow Kant's claim to have denied knowledge to make room for faith. Rather, Maimon revives something like the Aristotelian notion that the highest virtue and pleasure are found in philosophical contemplation. This results, Maimon claims, because both practical and theoretical cognition follow from the same notion of freedom:

> Just as I have produced the principle of practical cognition from the mere widening of the theoretical, so I find practical freedom from the mere widening of what is theoretically given as a fact, and this concept of freedom first makes possible the use of this principle (*GW* VII, 275 | KU 273).

Our cognitive situations in the theoretical and moral arenas are then identical; in each, the conflicts that characterize our cognitive capacities can be resolved only by assuming that our cognition is a ‘schema’ of an infinite intellect, which is to embrace a type of dogmatism that echoes Spinoza, Leibniz and Wolff.

The similarities between the theoretical and the practical realms allow for an explanation of the possibility of freedom, even though “this concept [of freedom] is capable of no empirical presentation.” (*GW* VII 241 | KU 241) Thought, Maimon argues, is an absolutely free activity of the faculty of cognition, which is not determined *a priori* by natural laws, but rather according to the laws of the faculty of cognition itself. The will that is related to the faculty of cognition (the will to think) is likewise not determined through objects of thought, but rather through the *a priori* form of thought (which precedes the actual thought of these objects). We thus have an instance of a free will in general (*GW* VII 242 | KU 240).

Although Maimon's account of freedom is related to Kant's position, Maimon diverges from the critical philosophy by insisting that since the moral law provides only the form of the determination of the will, the actualization of this form “must be connected to an originally agreeable feeling (which does not arise from habit).” (GW VII 243 | KU 241) This feeling, Maimon argues, must be understood not in terms of a particular sensuous desire, but rather as “abstracted from all individuality.” (*GW* VII 245 | KU 243) Here the close connection between the theoretical and the practical spheres is again important, for Maimon argues that the ‘abstract feeling’ is best understood in terms of a ‘drive for cognition’:

> Man considers himself as an object of nature, and consequently as a limited being, and yet, since his faculty of cognition extends to all possible objects, he finds himself in a position to strive to infinity, and to get ever closer to the infinite faculty of cognition (divinity). Can a greater worth for a being be thought than to get closer to divinity? And must not all other

> motives vanish in the face of the motives of cognition and morality (whereby all lofty preferences extend to outer actions)? Here we have the prevailing motive of morality, whose power no one who has considered the case can doubt (*GW* VII 246-7 | KU 244-5).

The role played by the pleasure of the striving after knowledge however, recedes in importance as Maimon becomes more skeptical about the possibility of explaining the motivations that lead to moral actions. Perhaps the clearest formulation of Maimon's later position is in ‘The Moral Skeptic,’ a late work from 1800, where a sketch of the difference between moral dogmatism and skepticism is provided. As in the theoretical realm, Maimon focuses on the problem of the legitimate application of universal rules to particular cases (a problem that Kant in the *Groundwork* is well aware of). Just as we can be skeptical of whether the category of causality is legitimately applied to particular intuitions, so too can the connection between the moral law and particular actions be called into doubt. While the moral law presents the rule of conduct that I ought to follow, there is no way, Maimon claims, to determine whether in fact I act only according to it, or whether other motivations have insinuated themselves into the action. Kant, of course, agrees with this point, but Maimon attempts to draw a more skeptical conclusion from it than Kant does. On Maimon's view, one cannot determine whether an action simply accords with the moral law “and hence possesses mere legality” or whether it in fact follows from the motive of duty itself, and as such lays claim to morality. This uncertainty arises, Maimon argues, because the moral character of an action is not immediately present to cognition. Rather, one can ascribe a moral character to a person or action only after excluding all other possible motives as insufficient to explain the action -- but, Maimon notes, such a strategy would require an ‘infinite faculty of cognition’ in order to accomplish this task. Given the uncertainty about motivations, Maimon argues that the moral law can at best be viewed as an “idea that provides only a regulative use (for legality).” (*GW* VII 547 | MS 285) As such, while the moral law presents a universal command, it cannot be shown to be the ground of human actions, since -- to employ a term from Maimon's theoretical philosophy -- there is no determinate relation between the moral law and particular actions. For Maimon, the moral law stands, as do the Kantian categories in the theoretical realm, as a ‘castle in the air,’ incapable of reaching the solid ground of particular actions.

7. Maimon's Influence on the Formation of German Idealism

Kant's high regard for Maimon was shared by a number of the important figures of the movements of German Enlightenment and Idealism. Mendelssohn, of course, had initially recognized the genius beneath Maimon's course exterior, and Reinhold too took Maimon seriously, although their relation soured after Maimon published a volume of their increasingly acrimonious correspondence without Reinhold's permission. On a much more positive note, Fichte wrote that his admiration for Maimon's talent “[k]nows no limit,” and he continues that “Maimon has completely overturned the entire Kantian philosophy as it has been understood by everyone until now.” (*Gesamtausgabe* III, 2: 275)

Although Maimon's positive system was of interest to the German philosophical community in the 1790s, his greatest influence was as a skeptic, and in particular as a critic of the ‘cognitive dualism’ that

characterized Kant's critical philosophy. The force of Maimon's objections to Kant was felt most directly by Fichte, who in the *Wissenschaftslehre* devotes considerable attention to Maimon's skeptical challenge to Kant. For Fichte, Maimon pointed out the fatal shortcomings of Kant's system, but failed to move beyond a skepticism about the prospects for knowledge. This is reflected in Fichte's claim that Maimon's position "would ground a skepticism that taught us to doubt our own existence." (*GA* I, 2: 369) Fichte sought to remedy this situation by developing a more thoroughgoing idealistic account of experience, one which placed the notion of 'positing' at the center of the system. Only in so doing, Fichte claims, can both Kant's dualism and Maimon's skepticism be avoided.

In the *Wissenschaftslehre*, Fichte expresses the central themes of Absolute Idealism: the centrality of a productive faculty of mind, as well as an embrace of a rationalist methodology and a concomitant rejection of any type of dualism. In this respect, the project of Absolute Idealism owes much to Maimon, who himself had developed just these themes in his various works. But where Fichte -- and Schelling and Hegel -- stand as optimists about the prospects for this type of philosophical inquiry, Maimon remains much less sanguine about the ability of finite minds to reach a final 'System' of philosophy. It is perhaps testament to the force of Maimon's skepticism that while the Systems of German Idealism have collapsed, the skeptical challenge Maimon poses for accounts of experience remains vital and forceful -- if unduly neglected -- today. Maimon, that is, anticipates key points of the contemporary debates about the nature of Givenness, and his skeptical position offers and interesting and novel perspective on discussions of the issue.

Maimon also seems to have played an important role in the reception of Spinoza in German Idealism. Maimon was not only the first to try to create a synthesis between Kantian idealism and Spinozistic pantheism (*GW* III 455), but he was also apparently the first to suggest that Spinoza's philosophy was not atheistic, but rather a strong though unorthodox religious view. Instead of characterizing Spinoza's philosophy as atheism, a view which denies Gods existence, Maimon argues that it should rather be called acosmism, insofar as it denies the reality of the diverse world and affirms the sole reality of God. This characterization of Spinoza was later adopted by Hegel (See Hegel's *Encyclopedia Logic*, sections 50 and 151, and his discussion of Spinoza in the *Lectures on the History of Philosophy*) and seems to play a central role in Hegel's perception of Spinoza.

8. Jewish Philosophy and Culture

Being raised in an East-European Jewish surrounding Maimon's thought was influenced by the major intellectual movements of this arena. Talmud, *Kabbalah*, contemporary *Hassidism* and medieval Jewish philosophy played a crucial role in the formation of Maimon's philosophy as well as the style of his writings. The strongest influence was that of Maimonides, whose unbiased and strict rationalism Maimon took as a guiding example throughout his life (even when he no longer adhered to Maimonidean metaphysics). Following Maimonides, Maimon held intellectual perfection as the ultimate human end, and saw moral perfection merely as means for achieving this end. Like Maimonides, Maimon argued that God's image in humanity is the intellect and that to the extent that we activate and develop our intellectual capacities we become closer and more similar to God.

Maimon's relation to the *Kabbalah* was a bit more ambivalent. While he had no sympathy for the anthropomorphic teachings of some of the major Kabbalistic works, Maimon attempted to disclose the rationalistic core of the *Kabbala,* which he identified with Spinoza's pantheistic teachings. In his early Hebrew writings Maimon develops the view that God is also the *material cause* of the world (i.e., that all things are merely predicates of God, who is their substratum). Since Maimon conceives God to be a pure intellect, the result is a genuine form of radical -- and pantheistic -- idealism. This form of idealism plays a significant role in Maimon's thought in the 1790s, and possibly also in the development of German Idealism in general.

Maimon also seems to borrow from Kabbalistic and contemporary Hassidic writings the idea of an infinite process through which one "strives to turn matter into form," though he will interpret this formula in metaphysical rather than ethical terms.

In his early Hebrew writings Maimon expresses a deep interest and curiosity about astrology and magic, an interest that he returns to as a contributor and editor of the *Magazin zur Erfahrungsseelenkunde*.

After his migration from Lithuania to Germany, Maimon entered the circles of the *Haskala* (the Jewish Enlightenment movement) in Berlin. Maimon shared with this circle the idea that there is a need to propagate the enlightenment and scientific education among traditional Jews; yet, he seemed to have a very different understanding of what Enlightenment is. While for the Berlin *Haskala,* 'Enlightenment' was primarily the attempt to acculturate the Jewish masses in order to allow their acceptance into modern German society, Maimon's idea of Enlightenment was that of propagating science and philosophy. This understanding of Enlightenment was deeply imbedded in Maimon's inheritance of Maimonidean philosophy, which took philosophy and the sciences to be the highest stages of religious work, through which one comes to know God in the deepest sense. This attitude is clearly demonstrated in Maimon's 1791 commentary on the *Guide of the Perplexed* -- *Giva'ath ha-Moreh* (Hebrew: The Hill of the Guide). In this work Maimon frequently interprets the claims of Maimonides according to 18th century science and philosophy (especially Kant). While this form of intentional anachronism reveals Maimon's view of philosophy as a perennial discourse, it was also designed to serve the propagation of modern science and thought among its readers (Maimon himself explains in a similar way Maimonides' decision to open his legal codex, the *Mishne Torah*, with a summary of Aristotelian first philosophy).

Like other members of the Jewish enlightenment, Maimon criticized traditional Jewish society, and primarily the Talmudists, for their prejudices and idleness. Yet, along with this straightforward criticism, Maimon also expressed a deep appreciation for the sharpness, devotion and moral character of the Talmudists. In his *Autobiography*, Maimon writes that he "would have to write a book, had I wished to answer all the unjust charges and ridicule brought against the Talmud by both Christian authors as well as wishing-to-be-enlightened Jews." (GW I 172 | LB I 172) Here Maimon gives a detailed picture of various streams and aspects of the Jewish culture. In most cases his account is a masterpiece of a thoughtful, thoroughly informed, and unbiased exploration of one's own culture.

Maimon's reception by both traditional and enlightened Jews was quite poor. In a few texts Maimon was

lumped together with Spinoza and Acosta to form "the great chain of Jewish heretics," but mostly Maimon's writings and philosophy were ignored. The traditional community could not forgive him his infidelity and his desertion of their ranks (A certain literary source tells us that in Maimon's funeral the children of the nearby Jewish community of Glogau ran after his coffin and threw stones on it. Maimon's corpse was buried at the margin of the Jewish cemetery in Glogau. When Maimon's friend, Graf Kalkreuth, asked why he was treated with such disrespect, he was told that "the edge of the cemetery is an honorary place designated traditionally for philosophers and their like"). For the enlightened Jews of Germany, Maimon was too much of an *Ostjude* and had too much sympathy for and similarity to the Talmudists. Furthermore, Maimon never took part in the attempt to define the "essence" of Judaism and by this to provide a theology that would imitate and be able to compete with modern Protestant theology. Being thoroughly knowledgeable about the variety of aspects and streams of Judaism, Maimon simply *could not* participate in this reductive project which was quite central to modern Jewish philosophy. Thus, in spite of the fact that Maimon's erudition in Jewish literature was hardly equaled by any other modern Jewish thinker, Maimon's name is omitted in many, if not most, 20th century surveys of modern Jewish philosophy.

Bibliography

Original editions of Maimon's main Works:

- *Versuchüber die Transcendentalphilosophie (=VT)* (Berlin: Christian Friedrich Voé und Sohn, 1790).
- *Gibeath Hamore* (Hebrew: *The Hill of the Guide*), (Berlin: 1791).
- *Philosophisches Wörterbuch, oder Beleuchtung der wichtigsten Gegenstände der Philosophie, in alphabetischer Ordnung (=PW)* (Berlin: Johann Friedrich Unger, 1791).
- *Salomon Maimon's Lebensgeschichte. Von ihm selbst geschrieben und herausgegeben von K. P. Moritz (=LB)*. (Berlin: Friedrich Vieweg, 1792-3).
- *Ankündigung und Aufforderung zu einer allgemeinen Revision der Wissenschaften: Einer königl. Akademie der Wissenschaften zu Berlin vorgelegt von Salomon Maimon*. (Berlin: Johann Georg Langhoff, 1792).
- *Bacons von Verulam neues Organon*, edited with notes by Maimon, 2 volumes (Berlin: Gottfried Carl Nauck, 1793).
- *Über die Progressen der Philosophie (veranlat durch die Preisfrage der königl. Akademie zu Berlin für das Jahr 1792: Was hat die Metaphisik seit Leibniz und Wolf für Progressen gemacht?)*, (Berlin: Wilhelm Vieweg, 1793).
- *Salomon Maimon's Streifereien im Gebiete der Philosophie*, (Berlin: Wilhelm Vieweg, 1793).
- *Die Kathegorien des Aristoteles ("With notes and as a propadeutic to a new thoery of thinking")*, (Berlin: Ernst Felisch, 1794).
- *Anfangsgründe der Newtonischen Philosophie von Dr. Pemberton*. (translated from the English with introduction and notes by Maimon), First Part (Berlin: Friedrich Maurer, 1793).
- *Versuch einer neuen Logik oder Theorie des Denkens. Nebst angehängten Briefen des Philaletes an Änesidemus (=VnL)*, (Berlin: Ernst Felisch,1794).

- *Kritische Untersuchungen über den menschlichen Geist oder das höhere Erkenntnié und Willensvermögen (=KU)*, (Leipzig: Gerhard Fleischer, 1797).

Modern editions and translations of Maimon's Works:

- Maimon, Salomon. *Gesammelte Werke (=GW)*, edited by Valerio Verra, 7 volumes (Hildsheim: Olms, 1965-1976).
- -----. *Salomon Maimons Lebensgeschichte*, edited by Zwi Batsch, (Frankfurt a. M: Insel Verlag, 1984).
- -----. Giva'ath ha-Moreh, edited by S.H. Bergmann and N. Rotherstreich (Jerusalem: Israeli Academy of Science, 1965 [Reprint 2000]). [Maimon's Hebrew commentary on the first part of Maimonides' *Guide of the Perplexed*].
- -----. *Letters of Philaletes to Aenesidemus*, trans. by George di Giovanni in di Giovanni and H.S. Harris (eds.*) Between Kant and Hegel: Texts in the Development of Post-Kantian Idealism* (Indianapolis: Hackett, 2001) [The only available English translation of any of Maimon's philosophical works].
- -----. *The Autobiography of Solomon Maimon*, translated by J. Clark Murray (Urbana and Chicago: University of Illinois Press, 2001)
- -----. *Commentaires de Maïmonide*, edited and translated into French by Maurice-Ruben Hayoun (Paris: Cerf, 1999). [A French translation of two major texts of Maimon dealing with Maimonides' *Guide of the Perplexed*: Chapters 1-10 of the second part of Maimon's *Lebensgeschichte*, and Maimon's Hebrew commentary on the *Guide*, *Giva'at ha-Moreh*]

Unpublished Manuscripts

- *Heshek Shlomo* (Hebrew: *Solomon's Desire*), Posen 1778. Currently held by the National and University Library, Jerusalem (MS 806426). [This 300 pages long manuscript is comprised of five -- rather independent -- works. The first text -- *Ma'ase Nissim* -- is a commentary on the homiletic book of the medieval talmudist, Nissim of Gerondi. The second text -- *Eved Avraham* -- is a super-commentary on Avraham Ibn Ezra's commentary on the Pentateuch and Psalms. The third text -- *Ma'ase Livnat ha-Sapir* -- is an attempt to harmonize some main Kabbalistic doctrines with the trachings of Maimoides. The fourth section -- *Ma'ase Hoshev* -- is an algebra textbook The fifth and last section -- *Avarchecha Bahya* -- is a short exposition of a biblical commentary by the 11th century Jewish philosopher, Bahya Ibn Pakuda].
- *Ta'alumoth Hochma* (Hebrew: *Mysteries of Wisdom*), Breslau 1786. Currently held by the Bodelian Library, Oxford (MS Mich.186).

Missing Manuscripts

Throughout his wanderings Maimon kept manuscripts of several works which he never published. After his death, Maimon's patron, Graf Kalkreuth, gave the manuscripts to Benjamin Fraenkel from the nearby Jewish community in Glogau. During the 19th century Maimon's manuscripts and letters were dispersed

and held by several prominent Jewish scholars and bibliophiles such as Abraham Geiger, Leopold Zunz and Heimann Michael. The collection of the latter -- which included Maimon's *Ta'alumoth Hochma* -- was purchased by the Bodleian library in 1848. Several other manuscripts found different ways to the collection of the Berlin *Hochschule für die Wissenschaft des Judentums* where they were held till World War II. Before and during the war the *Hochschule's* collection was smuggled out of Germany. The most important Maimonian MS held by the *Hochschule* arrived, after a long odyssey, at the National and University Library in Jerusalem. Other manuscripts of Maimon, held before the war by various individuals and institutions, are still missing. The authors of this entry participate in the search after these missing manuscripts, the most important of which are:

1. The Early Commentary on Maimonides' Guide. [A text which Maimon wrote before his first arrival in Berlin].
2. Maimon's translation of Mendelssohn's *Morgenstunden*.
3. Parts two and three of *Giva'ath ha-Moreh*. [In his *Autobiography* Maimon writes that these parts were ready to print and were supposed to be published soon thereafter. Apparently, the publishers were not interested in the work due to its lack of popular appeal].
4. A fragmentary commentary on Aristotle's Ethics.
5. *Die Mysterien der Philosophie* ("The Mysteries of Philosophy"). [Apparently, a complete book, ready for print].
6. *Über Logik* ("On Logic"). [Mainly remarks on Kiesewetter's book on logic].

Friedrich Heinrich Jacobi

Polemicist, socialite, and literary figure, Jacobi was an outspoken critic, first of the rationalism of German late Enlightenment philosophy, then of Kant's Transcendental Idealism, especially in the form that the early Fichte gave to it, and finally of the Romantic Idealism of the late Schelling. In all cases, his opposition to the philosophers was based on his belief that their passion for explanation unwittingly led them to confuse conditions of conceptualization with conditions of existence, thereby denying all room for individual freedom or for a personal God. Jacobi made this point, in defence of individualism and personalistic values, in a number of public controversies, in the course of which he put in circulation expressions and themes that resonate to this day. He was the one who invited Lessing, who he thought was walking on his head in the manner of all philosophers, to perform a *salto mortale* (a jump heels over head) that would redress his position and thus allow him to move again on the ground of common sense. He was also responsible for forging the concept of 'nihilism' -- a condition of which he accused the philosophers -- and thereby initiating the discourse associated with it. His battle cry, which he first directed at the defenders of Enlightenment rationalism and then at Kant and his successors, was that 'consistent philosophy is Spinozist, hence pantheist, fatalist and atheist'. The formula had the effect of bringing Spinoza to the centre of the philosophical discussion of the day. In the face Kant and his idealistic successors, Jacobi complained that they had subverted the language of the 'I' by reintroducing it on the basis of abstractions that in fact negated its original value. They had thus replaced real selfhood with the mere illusion of one.

But perhaps the most influential of Jacobi's formulas was the claim that there is no 'I' without a 'Thou', and that the two can recognize and respect one another only in the presence of a transcendent and personal God. Because of his defence of the individual and the 'exception', Jacobi is sometime taken as a proto-existentialist. This view must be balanced by the consideration that Jacobi was a defender of conservative values that he felt threatened by the culture of the day; that he never considered himself an irrationalist; on the contrary, that he thought his 'faith' to be essentially and truly rational; and that he tried more than once to develop a positive theory of reason. As a literary figure, he criticized the *Sturm und Drang* movement and dramatized in two novels the problem of reconciling individualism with social obligation. An exponent of British economic and political liberalism, Jacobi was an early critic of the French revolution, the destructiveness of which he considered the practical counterpart of the speculative nihilism of the philosophers.

1. Life and Intellectual Carrier

Like his junior contemporary Goethe (1749-1832), Friedrich Heinrich Jacobi was blessed with a long life, at least as measured by the standards of the time, and had the good fortune of witnessing in its course events that radically altered the cultural and political face of Western Europe.[1] Jacobi saw the Enlightenment (*die Aufklärung*) take hold in the German lands, and reach maturity in a peculiarly German cultural form. He saw it as it nurtured ideas of subjectivity and nature, and an interest in history, that were the precursors of later Romanticism. He saw it also as it was violently, even brutally, disrupted in the last decade of the eighteenth century by the events surrounding the French Revolution; and, finally, as it gave way to the new order of the nineteenth century. Despite long bouts of illness, Jacobi was deeply involved in these world shaking events, and actively contributed to them. He may not have had the political and military engagement of a Goethe, who could combine vast literary activities with weighty state responsibilities, but he was certainly an influential cultural and political commentator. Jacobi contributed enormously, throughout his active life, to the shaping of educated German public opinion. He carried on a most extensive correspondence with just about all the literary and political personalities of the day, and for many years also provided a meeting place for them at his country estate in Pempelfort, by hosting there a very popular literary salon. He was ably aided in this enterprise by his much admired wife Elisabeth von Clermont (universally known as 'Betty'). The list of names who frequented the salon, or with whom Jacobi entered in correspondence on different occasions of his life, reads as a Who's Who of the age. Heinse, Wieland, Goethe, Lavater, Herder, the Humboldt brothers, Diderot, Hemsterhuis, Hamann, Dohm, Georg Forster, the duchess Anna Amalia (Sachsen-Weimar), F. L. Stolberg, Fürstenberg, Princess Gallitzin and Sophie La Roche, counted among them, to mention only a representative segment.

In an age, moreover, in which friendship had been raised to the status of cult, Jacobi nurtured a number of intimate personal relations, all of which influenced his literary production in many ways. There was, for instance, his life long tempestuous relationship with Goethe -- punctuated as it was by periods of extreme intimacy and extreme alienation, and culminating in an irreparable break in the final period of Jacobi's career. (Nicolai, 1965) There was also his warm friendship with Hamann -- for the most part at a distance, since the two men managed to meet physically only once, in what were to be Hamann's last days, and this much anticipated meeting unfortunately devolved into a huge quarrel. As long as it lasted in the medium of letters, the friendship produced a body of correspondence widely recognized as one of the finest contributions to the German literature of the time. (Jacobi/Hamann, 1955-1979) There was then Jacobi's relationship with Princess Galitzin, much cultivated by Jacobi but overshadowed by the Princess's conversion to Catholicism and by her adoption of a quasi monastic style of religiosity

distasteful to Jacobi (Brachin, 1952; Trunk, 1955); his relationship with the Stolbergs, also embittered at some point by the Stolbergs'entrance in the Catholic Church (Brachin, 1952); with Lavater, whose pietism seem to have had a special attraction for Jacobi; with Basedow and Claudius,to both of whom Jacobi entrusted the education of his two surviving legitimate sons; and many other as well. These friendships, while engaging Jacobi emotionally, were perceived by him also as integral part of his intellectual life, since his fundamental belief, from beginning to end, was that thought must resist the lures of abstraction and remain throughout personal. Jacobi can perhaps best be characterized as a philosophical polemicist, but only in the sense that polemics is the natural medium of expression for a philosopher whose thought is essentially personalist, and for whom, therefore, (just as for Kierkegaard roughly half a century later) there is no serious thinking unless it is directed to someone in particular.

Jacobi also had the good fortune of belonging to a privileged segment of society. The Enlightenment as well as the French revolution presented him with more than just an intellectual challenge. In their different ways (which, as will be seen in Section 3, Jacobi however thought to have much in common), they both threatened the system of values that justified his social status. In the case of the French revolution, the threat was physical as well, since the events in France spilled over across the Rhine and were the cause for a time of much dislocation in his life. There were, in other words, interests other than purely intellectual that must have motivated his reaction to philosophy and philosophers and which would have to come under close scrutiny in a full study of Jacobi's life. They can however be abstracted from when the main interest, as here, is with the internal logic, or lack of it, of his view of things. A quick review of the main events and the more influential circumstances of his life is none the less in order, at least as signposts of his intellectual career.

Jacobi was born in Düsseldorf, on January 25, 1743, the second son of a well-to-do merchant. His older brother, Johann Georg, was the one selected by the family for an intellectual career, and he did achieve indeed a certain notoriety as a poet in the sentimental style of Gleim. The task of pursuing the commercial activities of the family was reserved for the younger Jacobi. There also were two daughters in the family, half-sisters to Jacobi. Neither of them married, and they eventually took over the management of Jacobi's household. According to his own account, (Jacobi, 1785: 8; 1787, 67ff; 1789, 328ff) Jacobi was temperamentally given to extremes of piety from his early youth, and was constantly troubled by questions concerning the existence of God and the endlessness of time. After confirmation, he joined a society of pietists in whose company these tendencies were reinforced. At sixteen, after a brief and disappointing apprenticeship in a Frankfurt commercial house, he was sent in 1759 to Geneva to develop there the social skills required for his appointed vocation. It is in that city that Jacobi, exposed to French ideas, as he matured socially, at the same time also formulated the basic beliefs that were to guide his intellectual career to the end. Under the tutelage of the famous mathematician G.L. Lesage, he became acquainted with traditional scholastic metaphysics. But he also worked on the writings of Charles de Bonnet, in which he found elements of psychological sensualism combined (allegedly even harmonized) with such Christian beliefs as the after-life, and read Rousseau's *Emile*(1761). Appended to the latter was the so titled 'Profession of Faith of a Savoyard Vicar', a manifesto upholding the rights of the 'heart'against the religion of reason popular among the rationalist philosophers of the day. Jacobi's resolution, at the time, was never to accept a system of thought unless it could be tested against actual existence and did not contradict his yearnings for God.

Back in Germany in 1762, Jacobi continued his philosophical studies. He eagerly read the essays submitted by Moses Mendelssohn and Kant in response to the competition sponsored that year by the Berlin Academy on the theme, 'Concerning Evidence in the Metaphysical Sciences'. According to his own account, Jacobi found Kant's essay much more convincing than Mendelssohn's, though first prize was awarded to the latter. (Jacobi, 1787: 74-75) He apparently also engaged in the study of Spinoza, and was impressed by Kant's essay on 'The Only Possible Ground for a Proof of God's Existence'. (Jacobi, 1787: 78-88) In 1764 he took charge of his father's business and -- after an affair with a housemaid with whom he conceived a son, both of whom (housemaid and son) he treated very shabbily by modern standards (Booy/Mortier, 1966) -- married the richly endowed Betty von Clermont. Together with her, he established the already mentioned literary salon at Pempelfort.

In 1772 Jacobi entrusted all his business affairs in the hands of his capable brother-in-law and accepted an invitation to join the governing body of the Duchy of Julich and Berg. His commission was to supervise the rationalization of local manufacturing and taxation practices. In 1779, he was also invited to Munich to conduct a similar reform in the Bavarian lands. In the same year, however, these official activities also came abruptly to an end. Jacobi's liberal views quickly came under attack in the Court at Munich, and, embroiled in bitter controversies, Jacobi returned to his native Düsseldorf. The literary fall out of this episode was the publication (Jacobi, 1779 (1) &(2)) of two essays in which Jacobi defended Adam Smith's economic views. The first essay was published while Jacobi was still in office in Munich, and was itself a major cause of his troubles there.

While engaged in these wordily affair, Jacobi had not abandoned his more humanistic interests. He had already ventured in some minor literary publications in association with his brother Georg while still busy with his commercial practice in Düsseldorf. In 1772, together with Wieland, whom Jacobi had come to know through his brother, he laid out the plans for a German journal patterned after the *Mercure de France*. The *Deutcher Merkur*made its appearance soon after, under Wieland's editorship. Jacobi used the journal as the vehicle of some of his occasional writings until 1777, when his collaboration with Wieland came to an end because of a bitter disagreement between the two men on political issues. (Jacobi, 1781, 1782) More significant for Jacobi's future were two other events that took place in the following years. The first was Goethe's visit to Pempelfort in the company of Basedow and Lavater. The encounter between the already famous poet and Jacobi that followed was, according to the reports left by both, of a highly emotionally charged nature. (Prantl, 1881: 579) Each man made a deep impression on the other. Jacobi's two novels, *Allwill's Briefsammlung*and *Woldemar*, owe their origin to that event. They were Jacobi's response to Goethe's ardent request, made during the visit, that he put in writing all that was closest to his heart. As things turned out, Goethe quickly cooled towards Jacobi, much to the latter's disappointment, and was later (1779) to prove especially cruel towards him by nailing to a tree ('crucifying'), to the great amusement of a large company, a copy of a just published new edition of the *Woldemar*(Stockum, 1957; Sudhof, 1959; di Giovanni, 1994: 52-53).

The other event occurred on the occasion of a long journey that took Jacobi, on July 5, 1780, to Wolfenbüttel, where Lessing was librarian at the Herzog August's library. Jacobi immediately paid a visit to the famous man, and it was there, while a guest at Lessing's house, that Jacobi engaged his host in that

now famous conversation in which, according to Jacobi's report, Lessing declared himself to be a Spinozist. (Jacobi, 1785: 10-45) This alleged revelation, made only a few months before Lessing's sudden death (1781), was to be the occasion of an exchange of letters between Jacobi and Moses Mendelssohn on the nature of philosophy in general and Spinozism in particular. Mendelssohn was well known at the time as Lessing's great friend, and as himself an artificer of the German Enlightenment. The exchange began in 1783 (Jacobi, 1785: 1), and continued in a period of time when Jacobi was deeply in sorrow because of the premature death of his beloved Betty (1784) and of a younger son, and was also suffering from bad health. As the result of an intricate and unpleasant set of circumstances -- one that was to provide fodder to opposing parties, in the dispute that soon followed, for questioning the integrity of both Mendelssohn and Jacobi -- the latter published the letters in 1785, complete with commentary, under the title of *Concerning the Doctrine of Spinoza in Letters to Herr Moses Mendelssohn*(Spinoza Letters).

Nobody could have predicted the extent and the fury of the controversy that the publication of the book caused. The controversy goes in the literature under the name of the Spinozism or the Pantheism Dispute. (Jacobi, 1916) Mendelssohn responded to Jacobi in writing (1786) but did not survive to see his reply in print. Already in bad health, he died. (4 January 1786) Jacobi responded to the reply. (1786) Both publications were notable for their bitterly personal tone. In retrospect, the controversy itself and the personal tone it assumed made sense, since the issues that Jacobi had raised had put into question the nature and the value of the new humanism being sponsored by the Enlightenment. As Goethe was to remark many years later, the controversy touched everyone in their deepest convictions.[2]Mendelssohn's death caused the debate to become even more personal, for his defenders (notably the Berlin's *Aufklärer*led by Nicolai) used it as an occasion to raise their hero to the status of martyr. One can gather a detailed account of the events, seen from Jacobi's point of view, in the latter's thick correspondence with Hamann of those years. (Jacobi/Hamann, 1955-1979) Hamann sided with Jacobi, though his irrepressibly eccentric self could not refrain from repeatedly poking fun at his friend. Two unforseen results of the episode were that Jacobi, until then a peripheral author, was propelled to the centre of public attention; and Spinoza's philosophy, already influential among the literary circles of the *Sturm und Drang*but otherwise traditionally rejected by the philosophers of the schools, became an object of philosophical discussion.

In 1787 Jacobi published *David Hume on Faith, or Idealism and Realism, a Dialogue*. In it he tried to clear himself of the charge of irrationalism brought against him because of his defence of the primacy of *Glaube*('faith'or 'belief') over reason in the still on-going controversy. Though appealing to the authority of Hume in this defence, Jacobi however also forcefully distanced himself from the latter's scepticism by declaring the sense in which he was rather a realist. The dialogue appeared in the wake of the publication of the second edition of Kant's *Critique of Pure Reason*(1787), and included an appendix in which Kant's transcendental idealism was severely criticized. The appendix was to become a *locus classicus*of anti-Kantianism. It eloquently restated all the main objections that had already been raised against the Critique since its first publication, and were to be repeated again against it, in a variety of forms, in the years to come. It is there that Jacobi made the famous quip: 'Without the presupposition [of the "thing in itself,"] I was unable to enter into [Kant's] system, but with it I was unable to stay within it'. (Jacobi, 1787: 223) His point was that, in presupposing the allegedly unknown 'thing in itself', yet by assigning to it the many functions that it played in his system, Kant was in fact demonstrating knowledge of it, thereby

contradicting his assumption of critical ignorance. The negative, even antagonistic, attitude that Jacobi assumed in this appendix overshadowed the fact, however, that he had always felt close in spirit to Kant. He had felt deeply hurt when Kant has sided with Mendelssohn[3]in the still on-going dispute. More important, it also overshadowed the fact that Jacobi had already developed a much more constructive critique of transcendental idealism, and had even offered a sophisticated alternative to it, in the body of the dialogue itself, while expounding his own realism. (See Section 2.2) This is an aspect of the dialogue that was not lost on some of Kant's own disciples, and was a factor in the development of post-Kantian idealism.

There followed a number of polemical writings directed at the Berlin *Aufklärer*. They reflected Jacobi's engagement in the famous 'Starck affair'-- a defamation suit, eventually lost by the plaintiff, brought by a certain J. A. Starck against the leaders of the Berlin Enlightenment.[4](Blum, 1912; di Giovanni, 1995) The case brought into question the legitimacy of freedom of the press. It also unfolded in the context of wide-spread conspiracy theories regarding the alleged efforts by secret societies, working under the manipulation of Jesuits or Papists in general, to undermine the rule of enlightened states. (See Section 4) In 1789 a second, much enlarged, edition of the Spinoza-Letters went to press. It reflected the recent publication of Kant's *Critique of Practical Reason*(1788). Among many additions, it included two prefatory sets of theses, the first denying human freedom, the second asserting it, together suggesting a resolution of the antinomy between nature and freedom quite different than the one proposed by Kant. It also included a number of new appendices, one of them sharply criticizing Herder, whose idea of God amounted, in Jacobi's opinion, to a half-baked pantheism.[5](Jacobi, 1789: 349-357) Jacobi's prefatory theses on human freedom were to be highly influential in the debate on the subject soon to break out between K.L Reinhold and C. C. E. Schmid. (di Giovanni, 2001) The debate quickly implicated many other personalities, Fichte among them.

The following years were marked by the visits to Pempelfort of Hamann, Stolberg, Herder, and Goethe (November 1792). Soon, however, political events were to overtake philosophical discourse. The beheading in Paris of Louis XVI (1793) shocked German public opinion, and occasioned Jacobi's lament in 'Accidental Outpourings of a Lonely Thinker'. (Jacobi, 1795) In 1794, as the French revolutionary armies crossed the Rhine and began bombarding Düsseldorf, Jacobi abandoned Pempelfort and undertook a long peregrination in the North, the guest of many friends in whose company he found comfort. (Prantl, 1881: 582) He settled for a time in Eutin. At this time he began the composition of 'Of Divine Things', a manuscript that he completed and published only later. In 1799 he became involved in the so called 'Atheism dispute'. This was a controversy surrounding the alleged atheism of Fichte which Jacobi himself had not initiated but in which he none the less played a leading role. At the request of Lavater, he wrote an open letter to Fichte (Jacobi, 1799) in which he restated all his objections to philosophy in general and the new idealism in particular, and reaffirmed his commitment to the primacy of faith. He also singled out Fichte as one who had realized all his misgivings about philosophy, since he had succeeded in restating Spinozism even from the standpoint of subjectivity. In a supplement (Supplement II) to the letter, Jacobi included a long comment on the nature of reason that he reprinted in the second volume of his collected works (1815)as an independent essay under the title of 'On the Inseparability of the Concept of Freedom and Providence from the Concept of Reason'. (Jacobi, 1812-1825) In 1802, he published 'On the Undertaking of Critique to Reduce Reason to Understanding'(Jacobi, 1802 (1)) -- this

latter directed particularly at Kant.

In 1804, Jacobi suffered a drastic reversal of financial fortunes but was spared a much reduced life-style by the call from Munich, late in the same year, to work there at the reorganization of the Academy of the Sciences. Jacobi accepted the invitation and in the following year moved to Munich. He remained there until the end of his life. Elected president of the reformed Academy in 1807, he unfortunately fed the animosity already felt in Munich against the foreigners recently invited to the Academy by implying in his inaugural speech a criticism of Southern Germany culture. (Jacobi, 1807) He also antagonized Schelling, at that time Director of the Munich Academy of the Arts. In 1809, in response to a writing of Schelling on human freedom that contained pointed criticisms of his understanding of Spinoza, Jacobi resurrected his unfinished manuscript ‘Of Divine Things’, completed it as an obvious polemic against the new nature philosophy that Schelling was promoting, and published it in 1811 under the title of ‘Of Divine Things and Their Revelation’. (Jacobi, 1811) The essay provoked a reply from Schelling which, in turn, provoked a counter reply by Jacobi. Thus arose the third of the major controversies in which Jacobi was involved -- one even more personal and bitter in tone than the earlier ones.

In 1812 Jacobi retired and, aided by his disciples J. F. Köppen and C. J. F. Roth, began the preparation of his collected works. (Jacobi, 1812-25) Since the turn of the century, he had begun to attract to his side such younger figures as F. D. E. Schleiermacher, J. F. Fries, and F. Bouterwek -- newly established academics whose thought he had inspired but who, in turn, influenced his final definition of the nature of reason. They all shared a scientific positivism which they combined with a contrasting moral/religious positivism -- this latter based on the assumption that higher values and the reality of divine things can be intuitively assessed by way of feeling. This younger generation helped to popularize some of Jacobi’s ideas and attitudes in the nineteenth century. Ironically, despite his life long opposition to Roman Catholicism, Jacobi exercised considerable influence in some German Catholic theological circles. (Weindel, 1950)

In 1817, Jacobi made reference in a letter to his friend Johann Neeb to a favourable review of the second volume of his collected works by Hegel. (Jacobi, 1825-27: vol. 2, 467-68; di Giovanni, 1994: 165-166) There was no apparent trace left in his comments of the anger that Hegel’s essay, ‘Glauben und Wissen’(‘Faith and Knowledge’), had aroused in him in 1801. (Jacobi, 1803: 221) Jacobi allowed that Hegel’s interpretation of his thought might be the correct one, and conceded that the two men might come to a meeting of minds, were it not for old age that prevented him from studying Hegel’s philosophy.

Jacobi’s extensive travels took him to London in 1786 and to Paris in 1801. (Prantl, 1881: 581, 582) Though first exposed to philosophy in a French cultural milieu, Jacobi was an Anglophile throughout his life and favourably compared British philosophers with the French *philosophes*. He credited the British for never having denied that virtue has value on its own; for never having made it just an instrument of happiness. The French, on the contrary, the moment their philosophizing progressed beyond mere common sense, were always all too prone in moral matters of falling into materialism. (Jacobi, 1812-125: vol. 5, 73-74)

Jacobi never saw the completion of the planned edition of his works. He died on March 10, 1819.

2. Main Philosophical Works

2.1 The Spinoza Letters (1st edition, 1785)

The Spinoza Letters is a cumbersome work, its disjointed composition indicative of the haste with which it was put together. The first edition opens with the text of a poem by Goethe that was however dropped in the second edition. The poem carried the name of its author but had been mechanically edited by Jacobi to bring out, by printing certain key phrases in relief, images especially important to him. Thus edited, the poem conveyed the idea that the pagan gods are Man writ large, and are therefore to be praised, since they reveal what is most noble in the human being. Brute nature is without feelings or discernment, whereas humans can judge, draw distinctions, and dare the impossible. They transcend nature. This was a humanistic message with which Jacobi agreed wholeheartedly. After a brief explanation of how the exchange of letters with Mendelssohn had originated, the main text goes on with a somewhat abbreviated version of the correspondence itself. The first letter gave an account of the conversation Jacobi had had with Lessing on the subject of Spinoza during his visit to Wolfenbüttel, and included the text of another poem of Goethe -- the *Prometheus*, one that had been the occasion of the conversation in the first place. This poem, hitherto still unpublished, was printed without the author's name (some thought it was Jacobi's own) and conveyed quite a different image of the gods than was found in the other poem. It suggested that they, no less than mortal men, are subject to the blind 'almighty time'that rules over all. In a universe thus ruled by 'eternal fate', they are therefore even more wretched than human beings, for the latter have at least the power to rebel against the order of things and thereby retain their dignity. At least as typified by Prometheus, human beings can rejoice in their own sufferings, and by this defiance uphold their individuality in the face of Fate.

In the rest of the letters we see Mendelssohn trying to play down the seriousness of Lessing's alleged admission to being a Spinozist. Since Mendelssohn thought at first that Jacobi was himself a Spinozist, we see him also attacking the basic doctrines of Spinozism as he understood them, while at the same time suggesting how they could be reformulated in an internally more consistent form to have them rejoin the accepted teachings of school metaphysics. Jacobi, for his part, was intent on displaying his scholarly (and indeed more accurate) knowledge of Spinoza's philosophy. In response to Mendelssohn's criticisms of Spinoza, he argued that Spinozism represented, on the contrary, a perfectly self-consistent position. It was school metaphysics that would logically lead to Spinozism, if its implications were just fully understood, not the other way around. Jacobi also gave an explanation for his sudden decision to publish the letters. Since Mendelssohn had announced the impending publication of his *Morgenstunden*,[6]a book in which, as Mendelssohn said, he would take up the issue of Spinozism, Jacobi thought that his opponent was unfairly trying to make a public head start on him in a controversy that was agreed would have to remain private before being brought to public attention by mutual consent. Jacobi then concluded the book with rambling extensive quotations from sundry theologians, and 'sealed'it (his expression) with an excerpt from Lavater.

Mendelssohn was bitterly to complain to Kant that Jacobi's volume was like a monster that sported Goethe for head, Spinoza as torso, and Lavater for feet. There was a point to his complaint. Yet, despite the many divagations and the pervading preachy tone of the text, there was a definite philosophical message that Jacobi was conveying. Philosophers are temperamentally inclined to reconstruct reality according to the requirements of explanation, in total disregard of the requirements of existence. They are possessed, as it were, by a logical fanaticism that leads them to mistake the abstractive principles of explanation for principles of existence. Since the individuality of things is the first victim of this confusion, yet individuality is the necessary condition of all existence, it follows that in the world as reconstructed by philosophers there is no room left for truly existing subjects -- least of all for agents who can seriously take responsibility for their actions and relate to one another as person to person, an 'I'to a 'Thou'. All that is most noble in human nature (as depicted in Goethe's first poem, Jacobi implies), notably the ability to make decisions and transcend brute nature, is thus denied, and there is no alternative left for human individuals, if they care to preserve at least a modicum of dignity, except to take pleasure in their avowedly only delusory sense of freedom (according to Goethe's second poem, as Jacobi also seems to imply). The much vaunted Enlightenment humanism, based as it was on the ideal of pure rationality was only a sham. It led in fact to 'nihilism'(a term, incidentally, that Jacobi made popular).

According to Jacobi's report of his conversation with Lessing, after a disquisition on his part regarding the devastating effects of a thought based on the demands of reason alone, and upon Lessing's apparent declaration of sympathy for Spinoza, Jacobi had urged upon the latter to perform a *salto mortale*(Jacobi, 1785: 17), i.e., a kind of jump, heels over head, that would redress his position. Enlightened philosopher that he was, Lessing had been walking on his head. The jump -- which Lessing humorously declined to execute citing old age as excuse (Jacobi: 1785, 33-34) -- would have brought him to his feet, back on the solid soil of common sense. Jacobi's obvious agenda, in other words, both at the time of this meeting with Lessing and later, in the exchange of views with Mendelssohn, was to attack the rationalism of the Enlightenment. Also implied, however, was a criticism of Goethe. The latter had spearheaded the *Sturm und Drang*reaction against the same rationalism that Jacobi was now condemning. Jacobi's veiled message was that the adepts of this new cultural phenomenon had failed to escape the rationalism of the philosophers, since the rebellious new humanism they advocated made sense only on the presupposition that the philosophers's conception of reality was the right one. It is the desire to convey this message that alone explains the otherwise puzzling presence in Jacobi's volume of the two poems by Goethe. To Jacobi's contemporaries, who lacked the background knowledge of Jacobi's special relationship to Goethe, and were even unaware of Goethe's authorship of the second poem, their inclusion in the volume remained a mystery to the end.

At any rate, whether Jacobi's agenda was directed at the Enlightenment or the *Sturm und Drang*, the presence of Spinoza both in his conversation with Lessing and the later controversy with Mendelssohn was clear. Quite apart from the fact that he had been the central object of discussion in Jacobi's first encounter with Goethe -- another circumstance that Jacobi's contemporaries could not know -- Spinoza was now being portrayed by Jacobi as the one philosopher who had had the courage to press the logicism of the philosophers to its ultimate limit, and to draw from it its inevitable conclusions. Spinoza had subsumed all reality under the one highest abstraction of 'substance', with the net result that any real distinction between one presumed individual thing and any other, and between all things and God, was

being denied. True generation, or anything connected with temporality, equally disappeared, except as mere illusionary phenomena. This was as nihilistic a conclusion as, in Jacobi's opinion, one could possible draw. In his eyes, therefore, Spinoza stood as the philosopher *par excellence*(an attribute, however, which he later conferred on Fichte). According to the formula that he drew, philosophy equals Spinozism, and Spinozism in turn equals atheism -- this last part of the equation being based on the assumption that, since Spinoza's God, viz. Substance, lacked the attributes of a person, it he could not satisfy the requirements of true religiosity.

One can understand, therefore, why Jacobi's attitude towards Spinoza could have been a source of confusion for Mendelssohn and later critics as well -- to the point that Jacobi himself was often taken to be a Spinozist. On the one hand, Jacobi pointed to Spinoza as an object lesson of all that is wrong with philosophical reason. On the other hand, he was praising him for being the most consistent of all philosophers (Jacobi, 1785: 27-29), and even defended him against those -- Mendelssohn included -- who, as he thought, detracted from his philosophy by their misguided attempts at 'saving'it from the consequences of its unmitigated rationalism. And there was another reason as well for Jacobi's otherwise puzzling predilection for Spinoza -- the Benedictus, as he once calls him, the 'Blessed One'. (Jacobi, 1799: 41) Spinoza knew that truth is its own criterion; that ultimately, therefore, it is not amenable to discursive reason but must be apprehended immediately on its own, intuitively. This was also Jacobi's position. His objection against the rationalism of the philosophers boiled down to precisely this -- that it was the product of a reason that had lost touch with its intuitive sources, and was therefore given to mistaking its own productions for the real thing. On this score, Jacobi thought that he had found a strange ally in the most rationalist of all philosophers.

Yet there was a serious problem in the Spinoza Letters. Jacobi never quite gave to understand what *he*,as contrasted with Spinoza, meant by 'intuition'. He says that philosophy must be 'historical'-- presumably, that it must take its starting point from the records of human actions and human events; that it must never abandon experience, or common sense. These, though vague and hardly the basis for a well defined position, were in themselves perfectly acceptable claims. But Jacobi then obscured them with his pious perorations at the end -- by citing, among others, the theologian Jerusalem, who thought that the task of philosophy is simply to elucidate the content of revealed faith, and Lavater, who believed in the ever present witness of miracles. He could easily give the impression, as he in fact did, that, by attacking philosophy and the philosophers, he was advocating a return to the blind acceptance of Biblical revelation; that, by 'intuition', he meant religiously inspired 'faith'. Lessing had suspected that much at the end of his conversation with Jacobi, according to the latter's own report. After the publication of the Spinoza Letters, his friends and admirers had no doubt about it. Led by Nicolai in Berlin, they undertook their campaign against Jacobi, branding him with obscurantism and religious enthusiasm -- these, in the eyes of the *Aufklärer*, the greatest of all possible sins.

2.2 The 'David Hume'(1st edition, 1787)

The dialogue that Jacobi published in 1787 carried the full title of *David Hume on Faith, or Idealism and Realism, A Dialogue*. It had originally been intended as three separate dialogues, as the structure of the

final product still betrays. It clearly falls into three parts, with an autobiographical interlude connecting the first and second which is the source of much of our knowledge about Jacobi's early philosophical education. Jacobi uses it as a vehicle for documenting how much, from the beginning, he had been temperamentally driven always to give priority to existence, as immediately apprehended, over any conceptual representation of it, and also for putting on record that, when still a young man, he had found this irresistible tendency of his best satisfied in Kant's two early essays, one on evidence in metaphysics and the other on the proof of God's existence. (Jacobi, 1787: 67ff) These autobiographical remarks come at the heel of a defence, in the first part of the Dialogue, against the accusation of irrationalism brought against him chiefly because of his use of the term 'faith'(*Glaube*, in German) in the Spinoza Letters. Jacobi's many polemical divagations apart, the main line of the defence is very simple. Hume also had used the term 'belief'(also translated in German as *Glaube)*for the kind of assent which is based on experience and is expressed in the form of judgement. Such an assent is immediate, a matter of feeling rather than ratiocination, and all the more unimpeachable precisely because reason alone would never induce it on its own. Now, Jacobi argues, in the Spinoza Letters he had used the term 'faith'(also *Glaube*in German) in the same sense, in order to claim that judgement of existence must be immediate. No process of ratiocination could produce the certainty that accompanies it. There was no 'irrationalism', therefore, either intended or implied. On the contrary, Jacobi had been forced to use the term, and to oppose it to reason, only because the philosophers had pre-empted the latter term, and had unduly restricted it to mean the kind of discursive conceptualization that abstracts from real things and is ultimately irrelevant to judgments of existence. But nobody had ever accused Hume of irrationalism. Why was the charge, then, being laid against him? (Jacobi, 1787: 29ff)

Jacobi's critics, in this case Hamann included, were quick to point out that the English 'belief'does not have quite the same meaning as the German *Glaube;*that the latter carries religious connotations best expressed in English by 'faith', even though there is only one German word *(Glaube)*to translate both 'belief'and 'faith'. Jacobi's point, however, was that he, as a matter of fact, had used the term to mean 'belief', in Hume's sense. Whether he was being disingenuous in pressing it, granted the profuse use of religious rhetoric with which he had padded his earlier book, is of course a good question. None the less, once Jacobi had thus appealed to Hume's authority for his defence, he was faced by the task of having to distance himself from the scepticism which was entailed in Hume's use of belief but did not in any way fall within his own purview. Jacobi thought of himself as a realist. (Jacobi, 1787: vi) The second part of the Dialogue is concerned precisely with this issue. Inasmuch as Jacobi had a well formulated theory of knowledge at this stage of his development, it is to be found there.

Distilled from the many twists and turns of dialogue style argumentation, the theory can be summed up as follows:

> (1) The starting point is the denial, because contrary to fact, of the fundamental assumption of classical empiricism -- namely, that experience begins with purely subjective representations, and that belief in external objects is arrived at only by way of an inference based on the passivity of some of these representations. This assumption inevitably leads to Hume's scepticism. Jacobi rejects it off-hand on the ground that, as a matter of fact, a subject could not be aware of himself -- aware also, therefore, of the alleged subjectivity of

some of his representations -- without defining his 'self'in opposition to some admittedly external object, i.e. without immediately referring his representations to something other than himself. The very possibility of subjectivity entails the possibility of objectivity. Jacobi's classical formula for this position is that there is no 'I'without a 'Thou'. (Jacobi, 1787: 63-65)

(2) Hume had of course denied that we have consciousness of any definite 'self'. Such a denial, however, is only possible according to Jacobi if one assumes a purely theoretical standpoint with respect to the 'self'. We act, and we become aware of ourselves precisely in action. (Jacobi, 1787: 102ff) Self-awareness originates in a subject's feeling of power that accompanies action. Jacobi cites Hume himself in support this claim, even though he then uses the claim precisely in order to overcome Hume's theoretical scepticism. The alleged feeling of power immediately implicates the presence to the subject of an external something that exists in itself and interferes with the felt power, but, in so doing, also provides a reality check for it.

(3) Representation is called into play as the reflective attempt on the part of the subject to sort out the differences between his own self and the external thing resisting his power. This is a formula that brought together in an original unity the three components of consciousness, namely feeling, sense representation, and reflective conceptualization, that Hume as well as Kant had instead sought to synthesize externally. Through a series of arguments, Jacobi then shows how it is possible to arrive at all the categories that Kant had proposed *a priori*by descriptively identifying, rather, the basic conditions that define the distance between the self and its 'other'. (Jacobi, 1787:111-121)

(4) It follows that 'reason'is not a faculty that supervenes to the 'senses'*a priori*, but a more refined form of otherwise fundamentally sensible representations. As Jacobi puts it, the greater the sensitivity of a subject, the greater his rationality also. The two, 'senses'and 'reason', are inextricably bound together. (Jacobi, 1787: 125-34)

In making this last point, Jacobi paraphrases Thomas Reid, without however mentioning him explicitly in this immediate context.[7]He apparently thought that he was deploying against Hume the same line of argument already advanced against him by his Scottish 'common sense'critic. He was also thereby clarifying what he meant by 'intuition'-- that supposed immediate apprehension of truth that gives rise to belief. It now appears that the intuition in question is a product of the 'senses'. It is not, however, anything blind, for -- as understood by Jacobi in the spirit of Reid, and certainly in contrast to both Hume's and Kant's notion of sensibility -- 'sensations'are not passive impressions of the mind but exhibit rather from the start a complex relation between subject and object that can then be developed into even more reflective (i.e. representational) forms. Jacobi actually says that he is dependent on Spinoza for the seminal idea of his present method of deriving reflective representations from the senses. (Jacobi, 1787: 120, note 25) More significant, however, than any reference to Hume, Reid, or Spinoza, is that he also refers to Kant and his transcendental method deliberately, thus betraying that *he*(Kant), rather than any of them, had been his main concern all along. (Jacobi, 1787: 119-20, &120, note 25) Jacobi had been

advancing a theory of knowledge that, in his opinion, could compete with Kant's. For it explained the basic facts of experience, and even explained the factual necessity of certain fundamental concepts arising in the course of it, without incurring the kind of formalism that, in his opinion and many of Kant's contemporary critics, affected Kant's own transcendental method. Jacobi's first representations were allegedly drawn from experience directly. They were not applied to it *a priori*, in the manner of Kant's categories which Jacobi regarded rather as nothing more than ‘prejudices of the intellect’.

But there was a difficulty inherent in Jacobi's proposed theory. It came out most poignantly in the third part of the Dialogue -- a part dedicated, for the most part, to an exposition of Leibniz's metaphysics. (Jacobi, 1787: 144ff) Here Jacobi portrays the German Leibniz as the champion of individuality, and also tries to show how it is possible to accept his Monadology if duly modified. The transition in the Dialogue between second and third part is performed rhetorically. There was, however, a conceptual basis for it. And it was in this, in the obvious logical connection between Jacobi's just suggested theory of experience and Leibniz's Monadology, that the difficulty lay. For the organic conception of rationality that that theory implied -- reason being nothing more than a more developed, more reflective, form of sensibility -- fitted well indeed with Leibniz's system. But it also clearly led to Leibnizian naturalism. And the idea that the ‘self’cannot be defined except in terms of an ‘other’, while also well fitted to the Monadology, also led to the equally Leibnizian position that everything in the universe is itself by reflecting everything else. Jacobi had however made his philosophical debut precisely by combating the assumption that everything can be explained by reference to everything else -- a position that he thought reflected the philosophers's logical enthusiasm for explanation and which he opposed because it ended up undermining human subjectivity.

Jacobi expressed hesitations about the Dialogue from the beginning. He eventually criticized it openly, attributing what he later thought was the confusion marring it to his lack, at the time of composition, of a clear conception of reason. Whether his later conception was to be any better, or whether the original text was truly confused, is of course a question open to discussion. At any rate, the presentment of an unholy alliance against Kant that Jacobi was unwittingly forging with schlastic metaphysics -- his otherwise natural foe -- is perhaps the reason for the abrupt, even puzzling, conclusion that he gave the Dialogue. Jacobi ends it with an unexpected renewed effusion of the same pious rhetoric we find at the conclusion of the Spinoza Letters. Indications are given that one can have direct experiential evidence of things supernatural. (Jacobi, 1787: 195ff) Indeed, on the naturalistic conception of reason earlier developed in the Dialogue, any evidence of the Divine would have to be obtained directly, on the evidence of miracles, as Lavater believed. This was perhaps a position dear to Jacobi's own heart, but it embarrassingly made him vulnerable again -- this is the puzzling part about this production of Jacobi -- to the charge of obscurantism that had been the purpose of the Dialogue to fend off in the first place.

2.3 The Spinoza Letters (2ndedition, 1789)

The much augmented second edition of Jacobi's first major work included a fuller documentation of the correspondence with Mendelssohn, and eight new supplements in which, among other things, Jacobi offered a more detailed exposition of Spinoza's philosophy (Supplements VI, VII) and a lengthy criticism

of Herder's version of Spinozism (Supplement IV). It was also prefaced with fifty-two propositions -- twenty-three purporting to defend the thesis 'Man does not have Freedom'; the remaining twenty-nine, the opposite thesis 'Man has Freedom'. The argument in defence of the first thesis is based on the assumption that human affairs are organized mechanistically, i.e. according to a concatenation of purely efficient causes that would make the being of each totally dependent on the external being of everything else. In defending the thesis Jacobi follows Spinoza closely. The mechanism at issue applies to the cognitive side of man just as much as to his bodily side. Consciousness, or representational being, is only a mirror of extended being. Whatever happens in the latter is repeated on the side of thought, though according to thought's own modality of existence. Thus, according to Jacobi, syllogistic thinking is mechanistic in nature, being driven by principles *ab ante*no less than any corporeal sequence of events. So far as the opposing thesis is concerned, Jacobi argues for it by retrieving a theme from the *David Hume*.If it is the case that a finite 'I'acquires identity only when confronted by an equally finite 'Thou', then, just as for the required interplay between the two one must assume on each side a source of 'passivity'that allows each to be limited by the other, so one must also equally assume in them a countervailing source of 'activity'. This source is irreducible. It follows that 'activity'and 'passivity'must be assumed to run across the world we know in every part of it. In some parts, the one element might well display a greater degree of intensity than the other; nowhere, however, can either element crowd out the other totally. It also follows that, though mechanism is both possible and necessary, a totally mechanistic organization of things that would *eo ipso*allow no room for individual freedom, i.e. one that would reduce all things to external relations, is an impossibility, for it would in fact reduce things to mere nothingness. (Jacobi, 1789: xxxv-xxxvi) It would make them totally passive. 'Passivity', however, has no meaning except in relation to 'activity'. The conceptual basis for denying the reality of individually attributable human act is thus removed.

The two theses, appearing as they did one year after the publication of Kant's *Critique of Practical Reason*, may be taken as a tacit criticism of Kant's strategy of defining the problem of freedom in the form of an antinomy. Jacobi's two theses do not constitute an antinomy because, from their perspective, any apparent opposition between mechanistic explanation and moral demands is already resolved in the propositions detailing the second thesis. Presupposed by both sets of propositions is the assumption, which Jacobi accepts, that beings (at least, created beings) exist in limiting relationships, and that such relationships entail an irreducible element of passivity as well as activity on both the sides entering into them. The difference between the two sets of propositions is that the second (the one defending freedom) respects this necessary condition of any relationship, whereas the first does not. Only the philosopher, because of his passion for abstractions, is tempted to conceive, on the one hand, a purely mechanistic relation, one which in fact negates activity altogether and thus removes the basis for the desired relationships; on the other hand, one which is purely active, exclusively spontaneous, and thus attains the same result by the opposite route. For this last point, Jacobi could have easily connected Kant's notion of freedom as purely spontaneous activity with Spinoza's *causa sui*. Only then, when one has thus given way to the philosopher's passion for abstractions, is one faced with the Kantian kind of antinomy -- a conflict of opposing yet conceptually valid views that can be controlled, though never truly resolved, only by appeal to the unknown.

In other words, the choice with which Jacobi confronted his readers at the opening of his new edition of

the Spinoza Letters was not between two conceptually valid yet contradictory claims, but between the anti-humanism of the philosophers -- based at it was on an abstraction -- and a humanism that on the contrary stays close to the facts of experience. In this respect, Jacobi was reaffirming the point he had already made to Lessing ten years earlier, namely, that the only way to deal with the irrational results of philosophizing is to know when to stop to philosophize. Ironically, however, he had used the same general paradigm of two interacting forces to define, in his two sets of propositions, both the system of mechanical causes and the system of freedom. This was a point that did not go lost. Fichte was soon to use the paradigm as his basis for resolving Kant's antinomy, by arguing that freedom requires as its counterpart the kind of mechanistic organization that scientific explanation demands. Where Jacobi had tried to circumvent the antinomy altogether by suspending philosophical reflection at the right moment, Fichte was to try to resolve it by prompting that same reflection to a higher level of abstraction instead. So far as Jacobi was concerned, the results of any such move could only be disastrous. And it was indeed against Fichte that, ten years later, he felt compelled to repeat in stronger terms than ever before his original interdiction against philosophers.

2.4 The Open Letter to Fichte (1799)

Many were the circumstances that precipitated the charge of atheism against Fichte and eventually led to his departure from Jena, not all of them of a philosophical nature. His early philosophical system did nothing, however, to help him.[8]In brief, Fichte's position was that the resistance that nature *de facto*poses to the exercise of human freedom should be interpreted as a product of freedom itself, inasmuch as the human self, by raising itself through abstractive reflection to the status of a pure 'I', thereby introduces new possibilities of being, in the face of which given nature necessarily assumes the appearance of a purely contingent, foreign, quantity. It has no meaning in itself except as a material on which the self can exercise its freedom by shaping it according to its intentions. The freer the self, the more insubstantial nature will appear to it, and the greater the possibility of rationalizing it through external means. Even if nature were not in itself a mechanical organization of mere appearances, it would have to be assumed by the free self to be such for the sake of freedom. This is of course an oversimplification. It conveys none the less an aspect of Fichte's early thought that could easily have given the impression that his system constituted the ideological justification for the kind of social engineering that was being done across the Rhine, in revolutionary France, in the name of Freedom. Many thought, at the time, that the *philosophes*had been the ones to hatch the revolution in the first place. And Fichte now seemed to confirm their worse suspicions. This fear of the revolutionary potential of his thought -- a fear, it must be said, not altogether ungrounded -- is what gave the debate surrounding his suspected atheism its special emotional tone.

In part it also explains the stridency of Jacobi's public reaction to Fichte -- even though privately, as person to person, Jacobi was concerned about the man's safety, and even considered possible venues of refuge for him. He declared Fichte as the true disciple of Kant -- the one who had brought the premises of Transcendental Idealism to their logical conclusions. He also revised his prior estimate of Spinoza. He had always portrayed the latter as the most consistent of all philosophers. He now recognized that the attribute belonged in truth to Fichte. *He*was in fact the philosopher *par excellance*-- the Messias of

Reason, as Jacobi now loudly proclaims him. (Jacobi, 1799: 2) For Fichte had extended the reach of philosophical abstraction, with which Spinoza had gone only so far as to exclude the possibility of subjectivity, to retrieve this subjectivity itself within its compass, as if it could be excogitated *a priori*out of pure thought. Fichte's idealism was a case of inverted Spinozism, of spiritual materialism. (Jacobi, 1799: 2-5) For Spinoza's substance, which explains all things by explaining none of them in particular, hence relegates the determination of individuals to the endless mechanism of external causes, was now being reintroduced as the product of pure reflection, as its first objectification. It was as if reflection dissolved all things in the ether of pure thought, out of sheer freedom, and then reassembled them again -- but now as a game, according to self-concocted rules. (Jacobi, 1799: 24-27)

All this infuriated Jacobi. No piece of his is as overflowing with religious language as this letter to Fichte. But the rhetoric exhibited here has none of the pious triumphalism, smacking of Lavater, that had vitiated his earlier productions. It seems born, rather, out of genuine fear in the face of what he thought was the ultimate nihilism of reason. Jacobi conceded that there was no argument against Fichte, no way of refuting him on his own conceptual grounds. He stood before him, therefore, as one who gave witness against the philosophers, forcing the audience to a choice between him and them. Against the universal norms of either Kant's or Fichte's morality, he stood rather as the champion of the exception -- the one who, for the sake of the individual, would dare profane the sacred altars, indeed to lie and even murder. (Jacobi, 1799: 32-33) This was a powerful individualistic manifesto that Jacobi was promoting, the kind not be heard again until Kierkegaard more than half a century later. But it had nothing to do with the asocial individualism typical of the *Sturm und Drang*movement that had been the cause of Jacobi's concern in his younger years. On the contrary, even before this commotion with Fichte, and probably with Goethe in mind, Jacobi had long been meditating on the place of the individual in society, and had formulated for himself a definite social theory. To gather an idea of it, however, we must turn to his more literary works, as we shall do in due place. (Section 3)

2.5 After 1800

The final period of Jacobi's life saw, among other things, two major publications and the undertaking of the editions of his collected work. We shall consider this last at the end, in the section 'Retrospect'(Section 5). As for the other two pieces, the first was a renewed and ever sharper attack on Kant's Transcendental Idealism, as the title indicated: 'On Critique's Attempt to Reduce Reason to the Understanding'. It was completed by Jacobi's disciple Köppen, as clearly indicated in the text itself; and published in 1802. Reduced to its bare minimum, the attack was based on three arguments, as follows:

(1) Kant had tried to establish the possibility of synthetic *a priori*judgements on the assumption of an object (= x) and of subject (= x) that we *ex hypothesi*cannot ever know but upon which the system of experience based on the said judgements none the less depends. The two (viz., the subject and object) constitute transcendental conditions of the possibility of the system of experience. Kant's attempt, however, entails an irresoluble difficulty. For although the assumed subject and object are factors that *ex hypothesi*fall *outside*the system of the *a priori*judgements to be validated (i.e., they are 'transcendental'), they can only be defined in terms of the concepts and distinctions that have meaning exclusively

*inside*that system. Kant thus finds himself in the embarrassing situation of negating, while at the same time affirming, the transcendality of the conditions of his system, thereby undermining the stability that the latter should derive from them. (Jacobi, 1812-25: vol. 2, 85-91)

(2) The same objection can be generalized in terms of the relation that obtains in Kant's Critique between 'reason'and 'understanding'. It is the task of reason, according to Kant, to define the extra-systemic conditions that make the system of experience possible. But, *ex hypothesi*, reason has no knowledge of these conditions. As defined by it, they are empty conceptual constructs that acquire meaning only to the extent that they are used by the understanding in its endless work of systematizing experience. To this extent, reason is totally subordinated to the understanding. Yet the latter *needs*reason. To the extent, therefore, that reason does satisfy this need with its ideas, it cannot help creating the illusion that, through them, it yields genuine knowledge -- that, logically, its conceptions are prior to those of the understanding. Now, Jacobi objected to what he took to be the existentially impossible requirement thus being imposed on reason, namely, that it should generate illusions for the sake of the understanding, yet be fully aware that such illusions are just *that*. (Jacobi, 1812-25: vol. 2, 81, 100-01, 115)

(3) The third objection, though repeated in a variety of ways, consists essentially in a criticism of Kant's analysis of the function of the understanding in experience. Even granted all the elements of Kant's transcendental psychology, notably, that sensations are *per se*amorphous mental impressions, that space and time can be at once intuitions and objects of intuition, that the categories are *a priori*concepts of the understanding -- assumptions these, all of which Jacobi in fact rejects, and against which he strenuously argues in the body of the essay -- even granted these, there still is an internal defect in Kant's system. The problem is that the two terms to be synthesized in any presumed *a priori*judgement of experience, namely, thought and sensations, are on their own too indeterminate to provide any clue as to how the object that should result from the synthesis would look like. So far as sensibility is concerned, such indetermination applies whether we take it according to its material content or its *a priori*forms of intuition, for 'space'and 'time', as defined by Kant, lack *per se*definite limits. (Jacobi, 1812-25: vol. 2, 77-79, 122ff, 134-35, 136-39) It follows that the determination, in actual experience, must be provided by the intervention of the imagination, and whether we take the latter in a psychological or transcendental sense, its contribution will necessarily entail an element of arbitrariness, and it will thus render any synthesis thereby attained vulnerable to sceptical doubt. Kant, in other words, fails to deliver on his promise of a knowledge, limited indeed to experience, but necessary within such limits. (Jacobi, 1812-25: vol. 2, 95, 97, 115ff, 118ff, 135, 150, 154ff)

The other major work of Jacobi in this last period,*Of Divine Things and Their Revelation*, was published in 1811. Jacobi had actually begun writing the piece ten years earlier, as the review of a recently published volume by a pietist writer, but had later picked it up again and completed in a totally different cast as a critique of Schelling's 'System of Identity'and of the new Philosophy of Nature connected with it. Evidence of its earlier purpose is still visible in the final text, beginning as it does with the discussion of a moral issue, namely, whether morality is to be based on virtue alone, or on natural happiness, or a combination of both. But then the text suddenly shifts to a long discussion of Kant's critical philosophy, the burden of which is however to demonstrate that Schelling's recent idealistic productions were but the logical consequences of precisely that philosophy. The treatment of Kant in this context is a strangely

qualified one. On the one hand, Jacobi praises him highly, showing him all the respect due to someone who had become an icon of German philosophical culture. He praises him because he had unequivocally recognized that a true God (presumably, such as morality demands) must be a person; also because he acknowledged that we have an immediate belief in God, freedom, and immortality, and 'belief'for Jacobi of course meant 'knowledge'; finally, because, just like Jacobi himself, he had tried to respect and harmonize the interests of reason, which are directed to God, and those of the understanding, which are directed to the senses. (Jacobi, 1812-25: vol. 3, 341-44; 351-52) Such praises, however, turn out to be hollow -- even a masked form of condemnation. For Jacobi's main thesis throughout the otherwise rambling work is that Kant, while upholding personalistic values, had in fact subverted them conceptually, the net product being Fichte's system of ideal materialism and now the openly naturalistic system of Schelling.

The kernel of Jacobi's argument was in fact still the same as the one presented in his earlier Kant essay (1802). The point there was that Kantian reason, though transcending the understanding, was none the less restricted in its knowledge to the limits of the latter and even subservient to it in the exercise of its powers. As a result, reason found itself in the strange situation of spontaneously generating belief that we have knowledge of transcendent realities, while at the same time having to recognize that any such knowledge is illusionary. Jacobi now further develops this point by arguing that Kant's critical system was explicitly intended from the start to serve the interests of science -- where by 'science'Kant meant first and foremost a cognition of the understanding directed at the objects of the senses. The understanding, however, despite its earth-bound nature, cannot help falling under the influence of the higher faculty of reason. It is caught up in reason's desire to behold all things under a transcendent single principle. And reason -- as a matter of fact, according to Jacobi -- does have an intuitive knowledge of things transcendent. But since the understanding cannot allow this knowledge, yet still needs reason as a higher regulative principle, it substitutes for reason's knowledge ideal constructs that are indeed also the products of reason, but are made up, however, of abstractions derived from the understanding. These abstractions then hide from the understanding and reason itself the transcendent knowledge that the latter enjoys *de facto*. For since reason naturally begins with the assumption of such a knowledge, yet cannot recognize it in the abstractions construed for the sake of the understanding, it ends up treating it as mere illusion. (Jacobi, 1812-25: vol. 3, 372-94)

Fichte's next obvious step was to remove the ground of the illusion by declaring the ideal constructs of reason to be themselves the objects of the transcendent knowledge that reason desires -- in effect, of identifying God with the logical order of things. And Fichte, according to Jacobi, quite consistently also took as the test of true personality the capacity on the part of a self to reconstruct the whole of nature*a priori*from the principles of that logic, thus reenacting ideally God's creative deed. In fact, however, such a logic was from the start the product of understanding's abstractions. It has no content of its own. The idealizing activities of a self cannot in fact be realized, therefore, except by attending to the material details of nature. And since, even when idealized, nature still remains 'nature', it follows according to Jacobi that in practice Fichte's idealism is but a form of materialism. Schelling's naturalism only made this fact explicit. In sum, the great hoax that according to Jacobi idealism had perpetrated -- starting with Kant and concluding with Schelling -- was to give to believe, not indeed that the human spirit can dispense with Things Divine, but that these things can be saved and attained in the impersonal medium of

nature.

Spinoza figures prominently in this last major work of Jacobi, just as much as he had in his first. Jacobi actually turns to him in order to clinch his own overall argument historically, and also, since Schelling now had no compunction about declaring the affinity of his system with Spinoza's, in order to vindicate the validity of his original claim -- the one with which he had made his philosophical public debut -- that philosophy equals Spinozism, and Spinozism equals atheism. Post-Kantian developments, in his opinion, had proved him right. His special concern in this late work was to establish the materialism of Spinoza. According to him, the great philosophical move with which which Spinoza founded his system was to distinguish extended substance from thinking substance while at the same time asserting the identity of the two in the one substance which is God. For Spinoza, therefore, extended substance was all that there is of objective being ('formal being', according to his terminology), i.e. of substantial and efficient being. Thinking substance is only the representation of it, with no content *qua* thought except that of substance, i.e. extended substance. It followed that, according to Spinoza, in order for thought to think God, or to think thought itself, it has to think extended substance. There is absolutely no other object available to it. And this, according to Jacobi, constituted an extreme form of materialism. Malbranche, Leibniz, and Berkeley -- again, according to Jacobi -- had recognized this materialistic implication of Spinoza's thought, and, in order to counteract it, they had all taken the obvious step of declaring 'extension'itself to be just an appearance. But then Kant came along, and he took the further step of declaring the 'self'itself an appearance, a series of representations with no content of their own and with no intrinsic substantial unity -- hence dependent for both on their phenomenal, spatially extended, objects. Through a circuitous route, through the language of subjectivity and appearance, Kant had thus reached the same materialistic position as Spinoza's. Jacobi had therefore been right when he had suspected from the beginning that Kantianism was but a form of inverted Spinozism. Fichte and Schelling had only worked out the implications of Kant's position, thereby rendering its Spinozist essence all too obvious. (Jacobi, 1812-25: vol. 3, 345-56, 431-32)

Important to note is the new terminology that Jacobi was using in this last work, and had already begun to use in the previous essay on Kant. He was now operating on the assumption that there is a distinction between 'reason'and 'understanding'-- where by 'reason'he meant the capacity for transcendent, unifying, principles; by 'understanding', the faculty of abstracting general representations from more particular ones. (Jacobi, 1812-25: vol. 3, 395ff, 400, 434-35) The distinction was, of course, Kantian in origin. The claim, moreover, that Kant had held 'reason'hostage to the abstractive requirements of the 'understanding'was one widely debated among his idealistic followers. Jacobi, however, was now using 'reason'to mean a faculty of intuitive knowledge of transcendent things. He was giving to it a positive noetic value. As used by him, therefore, the distinction between 'reason'and 'understanding'allowed him to draw what he thought was the crucial difference between himself and Kant. (Jacobi, 1812-25: vol. 3, 369-72) Whereas Kant had tried to harmonize the two faculties negatively, simply by keeping each within its appointed limits, Jacobi had revealed their harmony positively, by bringing to light the knowledge that reason actually contributes to experience, thus providing the positive matrix within which the understanding can operate.

In another way as well the distinction helped Jacobi -- or so he thought it did. From the beginning Jacobi

had been faced by the difficulty that, in order to oppose philosophical reflection and the nihilism that it brought in train, he had had to attack ‘reason’and to summon ‘faith’in its stead. He had thereby made himself vulnerable to the charge of ‘irrationalism’and ‘blind fideism’, a charge that he always strenuously rejected. So far as Jacobi was concerned, the true irrationalists were the philosophers. With the newly adopted distinction, Jacobi could now specifically direct to the ‘understanding’, or more accurately, to a ‘reason bound to the understanding’, the kind of criticism earlier directed quite generally to ‘reason’. He could then summon ‘reason’, with the new meaning attributed to it, to do the job previously performed by ‘faith’. In this way, he could more easily dodge the charge of ‘irrationalism’or ‘fideism’, for it was for the sake of ‘reason’-- that is, ‘true reason’-- that he could now claim he was waging his campaign against the philosophers. The problem, of course, was that Jacobi never quite clarified this new meaning of ‘reason’. He was apparently using the concept in the same way as he had previously used ‘faith’, namely, as denoting an intuitive faculty akin to feeling but at the same time sporting the clarity of a concept. And this was a combination of notes just as obscure when it went under the name of ‘faith’as it did when called ‘reason’. Whether the new distinction, and the new language that it made possible, in fact ever clarified Jacobi’s position is a question, therefore, open to debate.

3. Literary Works

Jacobi’s earliest publications, some done in collaboration with his brother Georg, were of a purely literary nature. And Jacobi continued to publish the occasional piece in this vein also later, when engrossed in philosophical debate. His reputation as a literary figure is mostly based, however, on his two novels, *Edward Allwill’s Collection of Letters*, and *Woldemar*. Both productions underwent a long process of development, and were published in different forms at different times. (David, 1913; Jacobi, 1957) The central character of the first, Edward Allwill, very likely underwent radical changes in the course of formation. We are only interested here with the substantially definitive form that Jacobi gave to them in the editions of, respectively, 1792 and 1794 (the latter as reproduced in 1820). Both, but the *Woldemar*especially, came in for devastating criticisms upon publication.[9]But they both also enjoyed a certain popularity. To call them ‘novels’in any modern sense of the word would be misleading. Both lack in serious dramatic action, and the characters, in each case, lack credibility. They are one dimensional figures, mouthpieces of Jacobi’s moral and social ideas rather than fully bodied personalities. In the case of the *Woldemar*especially, Jacobi seems to be talking about his characters rather than letting them act on their own. (David, 1913: 92 &notes) As narrations, the two pieces are in fact philosophical arguments thinly disguised by a veneer of imagination. Yet this feature, which might count as a fatal flaw from a purely artistic point of view, is precisely what makes them an indispensable part of Jacobi’s philosophical output.

As literary productions, the two pieces belong to the popular Enlightenment genre of *Erziehungsroman*, ‘education-novel’. In both cases the education at issue, as one would expect from the genre, is that of a *Herzensmensch*. This is the kind of human being who presumes to live by natural feelings alone but who, when confronted by actual social situations, learns (or fails to learn, to his ultimate destruction) that such feelings are insufficient for coping with the complexities of real life. Nature must rather be subjected to social discipline. Allwill and Woldemar, the main characters in Jacobi’s two novels, are both this type of

Mensch. Both behave as young men, though the biological age of Allwill is an object of discussion among the other characters of the novel, and he might well be taken to be young by vocation only.[10]Both seem to have come out of nowhere but to be at the moment deeply involved in the affairs of a family circle. Both are temperamentally gifted with strong feelings yet also given to highly abstract reflections -- both, sensitive products of nature yet refined products of thought at the same time. And it is as such juxtapositions of extremes that they play an influential and at times also disturbing role in the societies within which each has been admitted as an eccentric but also interesting permanent visitor.

The education that each of these ‘young men’undergoes (or should undergo) is shaped within the framework of these societies. From what we learn about Allwill, since early age, out of sheer natural impetuosity, he was given to some most extraordinary behaviour -- the kind that would have appeared to an outside observer as indicative, at times, of a noble and compassionate frame of mind; at other times, of sheer foolishness. So far as Allwill himself was concerned, however, such distinctions would have seemed immaterial, even meaningless. Allwill (whose name in German, as in English, means just *that*, ‘all will’) did whatever he did out of sheer impulse -- his only norm of action, the action itself. And now that he has grown older, he displays this character trait in the arena of speculative dispute as well. For the impetuous young man has also become a skilled dialectician, as we learn from a scene in which we see him deliver a long disquisition on the nature of knowledge in the course of a social gathering. (Jacobi, 1792: 143ff) Anyone familiar with Jacobi’s position on the subject can easily recognize that Allwill’s expressed views are also Jacobi’s. But Allwill apparently defends them only as an exercise in intellectual virtuosity, simply for the sake of winning a point. In a completely different mood, as he displays his skill at the clavier moments after his disquisition, we see him flippantly rejecting them all, in sharp contrast to the eagerness with which he has just defended them. (Jacobi, 1792: 156ff) Allwill thus moves in his social circle as an insubstantial being, one who appears now under one form, now under another, all the time giving the impression of an inner core that he in fact does not possess. Precisely for this reason, by holding out possibilities that are all the more interesting just because they are indefinite -- the illusionary products of a non-self -- he exercises in the eyes of some of the women in the circle the fascination of a seducer.

Allwill, who might have been taken as a beautiful product of nature in his first literary appearances, became an ever darker character as he developed at his creator’s hand. This is especially true in the 1792 edition of Jacobi’s novel, because of the singularly ominous shadow retrospectively cast upon his figure by a letter addressed to a certain ‘Erhard O**’, and carrying Jacobi’s own signature, added to it at the end. (Jacobi, 1799: 13) There are dark references in the letter to the demonic nature of this Erhard, and even more disturbing hints at the connection between his behaviour and the social destruction being wrought by the French revolution. It is significant that in the body of the novel itself, the one character who has penetrated through to the true nature of Allwill and recognizes the destructiveness of his character is a woman who, like him, does not belong to the family circle that provides the social context of the narration but, like Allwill again, preys upon the emotions of its members. She is a widow (Sylli is her name) who has lost her only child besides her husband, and now, left to her own, is tempted to despair. As a woman she stands according to the convention of the time for mother earth, and thus reveals another aspect of nature that might be lost in the brilliant figure of Allwill -- the one who would be the innocent first child of it. By itself, nature has no determinations. It is a shapeless, dark power, that

absorbs its products just as much as it gives birth to them. Sylli, if not saved by the intervention of her friends, is on the verge of collapsing into an inner maelstrom of painful feelings and distracted passions. Among all the women of the family circle, she understands and fears Allwill because, in her more elemental ways, she is just as seductive and destructive as he. Together, the two convey the message that Jacobi intends from the beginning of the narration. The cult of nature is just as misguided as the cult of reason; each is the reflection of the other. For nature as well as reason, when taken in abstraction from the social relations such as we see realized among the inner members the family circle in the narration, have no structure, no centre of gravity, and therefore only lead to a dispersion of existence. Those family members might not display the emotional power of a Sylli, or the brilliance of an Allwill. They actually look rather dull, and they certainly lack the intellectual acumen of Allwill. Yet, it is in the virtues they have developed by living in communion that Jacobi pins his hopes for a true humanity.

True rationality is social rationality. This is Jacobi's lesson in *Allwill*, and it is repeated in the *Woldemar*--though the central character there, Woldemar, while exhibiting the same propensity to abstract feeling and abstract thought as Allwill, is treated by Jacobi with much warmth. The character might well have been intended by him as a self-portrait. The novel itself, in its final form, was put together from two pieces originally published independently. (Jacobi, 1779 (3) (4)) The synthesis never quite worked. The result is that the narration is both convoluted and disjointed -- the overall theme, inasmuch as there is one, never transparent. There is, however, a sort of clarification at the end, in the emotional resolution of an intricate social situation that has been brewing from the beginning. Woldemar, unrealistic man of feelings that he is, has construed his whole world around the friendship he has developed with one of the women in the circle of friends he frequents. He has invested his whole existence in that friendship. And the woman has colluded with him. She has however secretly made an oath to her dying father, who has always distrusted Woldemar, never to marry him. And this secret, even though neither she nor Woldemar have ever considered marriage, none the less stands in the way of complete transparency in her relationship with Woldemar -- a circumstance for which she feels guilty. Woldemar learns about the secret by accident. His whole existence, built as it had been on the assumption of total reciprocity with the woman, is shattered. He totters on the verge of insanity. The woman, for her part, is distraught by the strange behaviour of Woldemar. But fortunately she learns about Woldemar's knowledge of her secret, and Woldemar in turn finds out about her knowledge of his knowledge. And this newly shared wisdom provides the basis for a renewed and healthier relationship between the two. Both acknowledge their guilt -- Woldemar, for having expected the kind of total transparency on the part of his woman friend that would have dissolved her individuality; the woman, for having used her individuality as an occasion for deception. The two are now ready to begin sharing their existence in friendship, fully aware of the dependence of each upon the other, yet also of the limits that such a sharing must respect.[11](Jacobi, 1812-25: vol. 5, 457ff)

The story might sound improbable to the modern ear, and Jacobi's lack of artistry does nothing to help it. Yet, despite its many flaws, the ethical lesson it was supposed to convey is interesting as well as significant. Jacobi was actually harking back to the notion of reason he had adumbrated even as early as the first edition of the Spinoza Letters. Rationality is constituted in the relationship between an &145;I'and a 'Thou', a relationship that respects the conditions of both its terms. Within the context of the *Woldemar*, this conclusion also brings resolution to a question discussed in a dialogue (the

*Waldgespräch)*introduced in the first part of the narration -- the question, namely, of the extent to which virtue depends on either nature or art. The answer is that it depends on both, provided that each is tested by the limits of actual human relations. At the conclusion of the novel, just as in the earlier dialogue, it is also clearly implied that the mutual respect that such relations demand from the individuals entering into them is possible only on the assumption of a 'Thou'greater than any human 'I'-- a 'Thou'whose transcendent pull forces the human 'I'outside its otherwise purely natural limitations.[12]Jacobi's last word, in his novels just as much as in his philosophical productions, always belongs to God.

4. Polemical Works

All of Jacobi's publications are polemical in nature. Some, however, were occasional pieces written with a particular event or situation in mind. Abstraction made of the perversely polemical tracts surrounding the Spinoza dispute and the controversy with Schelling (Jacobi, 1916, 1967), all of them are historically as well as conceptually interesting. Among them, we can single out a few.

In 1777, Jacobi's friend and literary collaborator C.M. Wieland (1733-1813) had published an essay arguing that power is the only source of legitimacy for political authority, hence that the only adequate form of government is a strictly autocratic one.[13]Right follows upon the physical ability to enforce obedience. Jacobi replied with a point-by-point rebuttal that was published only four years later. (Jacobi, 1781) For one thing, Wieland was historically wrong by misconstruing the actual origin of societies. Even more important, Wieland was conceptually wrong by not recognizing that 'moral law'and 'natural necessity'can be subsumed under the one concept of 'natural right'only in a very broad sense. Moral rights derive their force from the freedom of individuals, not from any consideration of natural laws. There is an irreducible difference between the domain of nature and that of freedom. On Wieland's assumption, it would follow that any human action is morally right by the very fact it is performed, just as a natural event gives evidence of its natural necessity by the very fact that it occurs. Thus the attempt on a monarch's life would be justified, provided it is successful. And even if, *per impossibile*, Wieland's assumption were right, and 'moral necessity'were identical with 'natural necessity', his conclusions regarding the state, Jacobi argues, would still not follow necessarily. A philosopher such as Spinoza, though a naturalist in moral matters, had arrived at directly opposite results so far as the organization of the state is concerned.

Jacobi renewed his political polemic in 1782, this time on the occasion of the publication by the historian Johann von Müller of a pamphlet entitled *The Travels of the Popes*,[14]in which, contrary to current 'enlightened'views, a positive revaluation of the role of the Popes in the Middles Ages was offered. Jacobi responded with a pamphlet of his own (Jacobi, 1782) in which he defended Müller's position -- not because he had any sympathy for Catholicism, or because he was opposed to secularism, but because he thought that the Popes's spiritual despotism was much to be preferred to the secular, allegedly enlightened, despotism of the princes. Especially interesting about the pamphlet is the essentially classical, even Platonic, conception of reason that Jacobi advances there, in defence, however, of a theory of individual liberalism which, in the eighteenth-century, was being defended rather on the basis of quite an opposite mechanistic conception of rationality.

In 1788, Jacobi published a piece in dialogue form in the *Deutsches Museum*. (Jacobi, 1788)He did it in the midst of the notorious Starck affair, and in response to the campaign being waged at the time by the Berlin *Aufklärer*against the pious religiosity of people like Lavater -- a religiosity which they took as a form of crypto-Catholicism, and as an attack on the universal religion of reason which they promoted. (Blum, 1912) The dialogue is between a pious believer and an enlightened philosopher. The believer's main point is that the philosopher has the right indeed to criticize faith. But the believer has just as much right not to accept the philosopher's portrayal of his faith. For, at the abstract level of conceptualization at which the philosopher operates, he is in no position even to recognize the true nature of the object of his attack. He cannot understand that there is nothing in what he says abstractly about God and the world that has not already been known by the believer from time immemorial in the medium of the latter's historical faith. The philosopher, moreover, forgets that his philosophy has a history as well; that its past is shrouded in a faith on which it still depends for the meaning of its abstract conceptions. By attacking faith, therefore, the philosopher risks undermining his own world of meaning.[15]

In 1802, Jacobi published a short piece (Jacobi, 1802 (2)) in response to a prophesy made by G. C. Lichtenberg, a well known science popularizer of the day,[16]to the effect that some day, as science progresses in its efforts at reducing matter to the laws governing it, our world will become so refined in our eyes that it will be just as laughable to believe in God as is now to believe in ghosts. Jacobi replied with a prophesy of his own, imitating the Gospels's account of the last days. The day prophesized by Lichtenberg will come indeed. But, after a while yet, as the world becomes even more refined, the sages will reverse their judgements. And then -- that will be the end of all things -- they will believe in nothing but ghosts. They will be like God, in the knowledge that being and substance are everywhere but ghosts. (Jacobi, 1811: 3-4) Jacobi reproduced the piece at the opening of his *Of Divine Things and their Revelation*in 1811, in obvious parody of Schelling's philosophy of nature.

5. Retrospect

The first volume of Jacobi's collected works was published in 1812; the second, in 1815. This last is especially important because it contains, added to the text of the *David Hume,*a long new Preface intended by Jacobi, as the title indicates, also as Introduction to his life long philosophical production. ('Preface and also Introduction to the Author's Philosophical Collected Works', Jacobi, 1812-25, vol. 2) In the piece, Jacobi tried to sum up his intellectual odyssey by articulating the interest that had motivated it from beginning to end, and thereby also to bring some systematic unity to what might otherwise have appeared a scattered philosophical production. Jacobi was obviously sensitive to the charge of irrationalism that had repeatedly been brought against him over the years, and anxious to disarm it. He appealed to the distinction between 'reason'and 'understanding'that he had adopted from around 1800 to argue, as he had already done in *Of Divine Things*, that the kind of knowledge he had earlier presented under the rubric of 'faith'should be understood rather as a product of 'reason'-- a 'reason'properly understood, of course, as an intuitive faculty for the immediate apprehension of such eternal verities as the Good, the True, and the Beautiful. (Jacobi, 1812-1825, vol. 2, 1815: 59-63 and *passim)*He accordingly edited the 1787 text of the *David Hume*, attributing what he thought was the

inconclusiveness of the dialogue to his yet unclarified concept of 'reason'at the time of the first edition. He added long footnotes to it, and even modified some crucial passages of the text itself -- a circumstance, incidentally, for the most part ignored by later commentators -- in an obvious effort to dispel the naturalism otherwise clearly implied in the original text.[17]While thus distancing himself from any possible evidence of naturalism, Jacobi however also tried to deflect the accusation, sometime brought against him even by friends,[18]that he was against science. He tried to compensate for his past repeatedly made remark that science is but a game of abstractions (Jacobi, 1799: 22-27) by reasserting now, as he had already done in *Of Divine Things*, that, without the understanding's power to synthesize in the medium of abstract representations the content of sensations, reason, just like the senses, would have no form and hence no cognition of itself. (Jacobi, 1812-25: vol. 2, 58, 110)

How successful these defensive tactics were is open to discussion. The additions and modification made to the *David Hume*only succeeded in disrupting Jacobi's earlier theory without offering a credible new resolution to it. Moreover, as already remarked, it made little difference replacing 'faith'with 'reason'when the meaning of the latter remained just as unclarified as that of the earlier term. And Jacobi's positive remarks about science did not come unqualified. Jacobi also stressed that, however necessary the functions of the understanding, the latter is none the less still naturally prone to naturalism and to the atheism consequent upon it. The question could naturally be asked how, on Jacobi's premises, reason was *both*dependent on the understanding for its form yet naturally exposed to falsification at its hand. One could legitimately doubt, as Friedrich Schlegel had done earlier in a review *of Of Divine Things*, whether Jacobi had truly made peace with reason.[19]None the less, despite all ambivalence, there was no doubt about Jacobi's motivation throughout. Jacobi had always perceived himself as the champion of personalism, of human individuality and of human transcendence over nature -- values these, that he had always thought threatened by the rationalism of the Enlightenment. At the end of his life, reviewing his long struggle against Kant's Critique and its idealistic aftermath, he judged the struggle justified. For, as he thought events had demonstrated amply, that idealism was but a more sophisticated form of traditional metaphysics, and had indeed led to the same naturalism.

A measure of the great influence that Jacobi had in his own lifetime, and continued to have in the rest of the nineteenth century, is that he was the first to put in circulation the term 'nihilism', and to inaugurate the discourse associated wit it. Ironically, however, more often than not that influence did not work itself out in ways Jacobi himself would have wanted. He had been the one to bring Spinoza to the centre of philosophical discussion, and many were to be the young philosophers (Schleiermacher among them) who were first exposed to his pantheism through Jacobi's intermediary. Rather than rejecting it, however, as Jacobi would have expected, they often embraced it enthusiastically. Jacobi's influence on Fichte can also not be overestimated. And his crisp formulation of how Kantian idealism stood with respect to Spinoza's philosophy of substance -- namely, that it repeated the latter in subjective terms, the result being that, while it reintroduced the language of personalism, it also subverted it by changing its meaning -- caught indeed the imagination of many nineteenth century philosophers. But these took it to mean that the values of the old morality had run its historical course, and that it was high time to reestablish humanism on a new foundation. And this was a conclusion that Jacobi would have found just as abhorrent as he had found the French revolution.

Because of Jacobi's insistence on the primacy of immediate existence over reflective conceptualization, and of the rights of the 'exception', the possibility is there to interpret his position as case of proto-existentialism, and to treat him, just as Kierkegaard, as an essentially religious thinker. (Beiser, 1987) Indeed, some of the language Jacobi uses, and the themes he explores, are to be found in Kierkegaard again. (Whether the latter was himself an existentialist is, of course, itself an open question.) One must however keep in mind that the language of the 'leap of faith'does not belong to Jacobi. The *salto mortale*he had proposed to Lessing was no leap into the unknown but, according to his explicit testimony, a jump that would have brought Lessing, who had been walking on his head in the manner of philosophers, back to his feet. (Jacobi, 1787: 62; 1789: 353) And as for the religious outpourings that pervade his writings, and often mar them, they must be measured against what Jacobi himself had to say about his religiosity when confiding to Reinhold late in life. As he said, his problem, the source of his many ambiguities, was that, though temperamentally endowed with a Christian heart, his mind was just as temperamentally pagan. (Jacobi, 1825-27: vol. 2, 478) And there are testimonies to the effect that he always kept himself at a psychological distance from Christian believers. (di Giovanni, 1994: 42) At the end, he identified with 'reason'what he had earlier referred to as 'faith'. Also to be kept in mind is that the personalist values that Jacobi championed were Enlightenment values as well. Jacobi belongs very much to his times. To label him 'an anti-Enlightenment figure', as is routinely done, is perhaps misleading.

In sum, Jacobi's figure, including its place within the Enlightenment, is much more complex than usually assumed, and still in need of discussion. It might well be that the secret of this complexity is that Jacobi, just like Kierkegaard after him, was motivated by deeply conservative beliefs which he saw threatened by the culture of the day; but, again like Kierkegaard, in trying to reassert them, developed a language that was later to be used, contrary to anything he would have ever imagined, to undermine them instead.

Stanford Encyclopedia of Philosophy
Notes to Friedrich Heinrich Jacobi

Notes

1. For a detailed sketch of Jacobi's life, the article in the *Allgemeine Deutsche Biographie* (Prantl, 1881) is still the best but must be supplemented with more recent discoveries. (Booy/Mortier, 1966). Basic information is drawn from Jacobi's autobiographical comments scattered throughout his works (Jacobi, 1812-1825, 1787, 1785) and enriched from his massive correspondence and the correspondence of third parties relating to him.

2. Johann Wolfang von Goethe, *Dichtung und Wahrheit*, III, p. 681. In *Sämmtliche Werke*, eds Richter, K. *et al.*, vol. 16. München: Hauser, 1985-.

3. Kant reacted to the dispute with his essay 'Was heißt sich im Denken Orientieren?' ('What Does It Mean to Orient Oneself in Thought,' *Berlinische Monatsschrift*, 8(1786): 304-330). Without endorsing Mendelssohn, whose metaphysics he could not have accepted, he none the less showed that his sympathy lay on his side. See also, di Giovanni, 1994: 32, note 70.

4. Johann August Starck, theologian and in his days renowned preacher at the court of Darmstadt, became at some point deeply involved in the shadowy side of Masonic internal politics. He apparently zealously conspired to establish within the order an 'ecclesiastical branch' that would incorporate in its ceremonials older rituals allegedly going back to the Mediaeval Templars. For this intriguing, he was repeatedly criticized on the pages of the Berlinmonatsschrift and of the Allgemeine deutsche Bibliothek, and accused of obscurantism. He was connected by the two journals with what at the time was widely feared to be a plot by the Jesuits to undermine Protestant enlightened society. Starck reacted by suing the two editors of the Berlinmonatsschrift (F. Gedike and J. Biester) for defamation of character. The courts found in favour of the two editors, on the ground that it was in the interest of the press to expose perceived dangers to society.

Friedrich Wilhelm Joseph von Schelling

Friedrich Wilhelm Joseph von Schelling (1775-1854) is, along with J.G. Fichte and G.W.F. Hegel, one of the three most influential thinkers in the tradition of ‘German Idealism’. Although he is often regarded as a philosophical Proteus who changed his conception so radically and so often that it is hard to attribute a clear philosophy to him, Schelling was in fact often an impressively rigorous logical thinker. In the era during which Schelling was writing, so much was changing in philosophy that a stable, fixed point of view was as likely to lead to a failure to grasp important new developments as it was to lead to a defensible philosophical system. Schelling’s continuing importance today relates mainly to three aspects of his work. The first is his Naturphilosophie, which, although its empirical claims are largely indefensible, opens up the possibility of a modern hermeneutic view of nature that does not restrict nature’s significance to what can be established about it in scientific terms. The second is his anti-Cartesian account of subjectivity, which prefigures some of the best ideas of thinkers like Nietzsche and Jacques Lacan, in showing how the thinking subject cannot be fully transparent to itself. The third is his later critique of Hegelian Idealism, which influenced Kierkegaard, Marx, Nietzsche, Heidegger, and others, and aspects of which are still echoed in contemporary thought by thinkers like Jacques Derrida.

1. Career

Schelling was born in Leonberg near Stuttgart on 27 January 1775. He attended a Protestant seminary in Tübingen from 1790 to 1795, where he was close friends with both Hegel and the poet and philosopher Friedrich Hölderlin. He moved to Leipzig in 1797, then to Jena, where he came into contact with the early Romantic thinkers, Friedrich Schlegel and Novalis, and, via Goethe’s influence, took up his first

professorship from 1798 to 1803. From 1803 to 1806 he lived in Würzburg, whence he left for Munich, where he mainly lived from 1806 onwards, with an interruption from 1820 to 1827, when he lived in Erlangen. He moved to Berlin in 1841 to take up what had, until Hegel's death in 1831, been Hegel's chair of philosophy. Although his lectures in Berlin were initially attended by such luminaries as Kierkegaard, Engels, Bakunin, Ranke, Burkhardt, and Alexander von Humboldt, he soon came to be largely ignored by most of the leading thinkers of the day. It is clear, however, that his philosophical thought still influenced many who rejected him on mainly political grounds. He died on 20 August 1854 in Bad Ragaz, Switzerland. Schelling's influence on many directions in modern philosophy has been seriously underestimated in the English-speaking world, though this underestimation is now beginning to be countered by renewed attention to his work.

2. Transcendental Philosophy and *Naturphilosophie*

The significance of the work of the early Schelling (1795-1800) lies in its attempts to give a new account of nature which, while taking account of the fact that Kant has irrevocably changed the status of nature in modern philosophy, avoids some of the problematic consequences of Kant's theory. For the Kant of the *Critique of Pure Reason* (1781, 1787) nature is largely seen in the 'formal' sense: nature is that which is subject to necessary laws. These laws are accessible to us, Kant argues, because cognition depends on the subject bringing necessary forms of thought, the categories, to bear on what it perceives. The problem this leads to is how the subject could fit into a nature conceived of in deterministic terms, given that the subject's ability to know is dependent upon its 'spontaneous' self-caused ability to judge in terms of the categories. Kant's response to this dilemma is to split the 'sensuous' realm of nature as law-bound appearance from the 'intelligible' realm of the subject's cognitive and ethical self-determination. However, if the subject is part of nature there would seem to be no way of explaining how a nature which we can only *know* as deterministic can give rise to a subject which seems to transcend determinism in its knowing and in its ethical doings. Kant himself sought to bridge the realms of necessity and spontaneity in the *Critique of Judgement* (1790), by suggesting that nature itself could be seen in more than formal terms: it also produces self-determining organisms and can give rise to disinterested aesthetic pleasure in the subject that contemplates its forms. The essential problems remained, however, that 1) Kant gave no account of the genesis of the subject that transcends its status as a piece of determined nature, and 2) such an account would have to be able to bridge the divide between nature and freedom.

The tensions in Schelling's philosophy of this period, which set the agenda for most of his subsequent work, derive, then, from the need to overcome the perceived lack in Kant's philosophy of a substantial account of how nature and freedom come to co-exist. Two ways out of Kantian dualism immediately suggested themselves to thinkers in the 1780s and 90s. On the one hand, Kant's arguments about the division between appearances and things in themselves, which gave rise to the problem of how something 'in itself' could give rise to appearances for the subject, might be overcome by rejecting the notion of the thing in itself altogether. If what we know of the object is the product of the spontaneity of the I, an Idealist could argue that the whole of the world's intelligibility is therefore the result of the activity of the subject, and that a new account of subjectivity is required which would achieve what Kant had failed to achieve. On the other hand, the fact that nature gives rise to self-determining subjectivity would seem to

suggest that a monist account of a nature which was more than a concatenation of laws, and was in some sense inherently ‘subjective’, would offer a different way of accounting for what Kant’s conception did not provide. Schelling seeks answers to the Kantian problems in terms that relate to both these conceptions. Indeed, it is possible to argue that the conceptions are in one sense potentially identical: if the essence of nature is that it produces the subjectivity which enables it to understand itself, nature itself could be construed as a kind of ‘super-subject’. The main thinkers whose work establishes these alternatives are J.G. Fichte, and Spinoza.

The source of Schelling’s concern with Spinoza is the ‘Pantheism controversy’, which brought Spinoza’s monism into the mainstream of German philosophy. In 1783 the writer and philosopher F.H. Jacobi became involved in an influential dispute with the Berlin Enlightenment philosopher Moses Mendelssohn over the claim that G.E. Lessing had admitted to being a Spinozist, an admission which at that time was tantamount to the admission of atheism, with all the dangerous political and other consequences that entailed. In his *On the Doctrine of Spinoza in Letters to Herr Moses Mendelssohn*, (1785, second edition 1789), which was influenced by his reading of Kant’s first *Critique*, Jacobi revealed a problem which would recur in differing ways throughout Schelling’s work. Jacobi’s interpretation of Spinozism was concerned with the relationship between what he termed the ‘unconditioned’ and the ‘conditioned’, between God as the ground of which the laws of nature are the consequent, and the linked chains of the deterministic laws of nature. Cognitive explanation relies, as Kant suggested, upon finding a thing’s ‘condition’. Jacobi’s question is how finding a thing’s condition can finally ground its explanation, given that each explanation leads to a regress in which each condition depends upon another condition *ad infinitum*. Any philosophical system that would ground the explanation of a part of nature thus ‘necessarily ends by having to discover *conditions* of the *unconditioned*’. For Jacobi this led to the need for a theological leap of faith, as the world’s intelligibility otherwise threatened to become a mere illusion, in which nothing was finally grounded at all. In the 1787 Introduction to the first *Critique* Kant maintains this problem of cognitive grounding can be overcome by acknowledging that, while reason must postulate the ‘unconditioned (...) in all things in themselves for everything conditioned, so that the series of conditions should thus become complete’, by restricting knowledge to appearances, rather than allowing it to be of ‘things in themselves’, the contradiction of seeking conditions of the unconditioned can be avoided. As we have already seen, though, this gives rise precisely to the problem of how a subject which is not conditioned like the nature it comes to know can emerge as the ground of knowledge from nature.

The condition of the knowledge of appearances for Kant is the ‘transcendental subject’, but what sort of ‘condition’ is the transcendental subject? The perception that Kant has no proper answer to this problem initially unites Schelling and Fichte. Fichte insists in the *Wissenschaftslehre* (1794) that the unconditioned status of the I has to be established if Kant’s system is to legitimate itself. He asserts that ‘It is (...) the ground of explanation of all facts of empirical consciousness that before all positing in the I the I itself must previously be posited’, thereby giving the I the founding role which he thought Kant had failed adequately to explicate. Fichte does this by extending the consequences of Kant’s claim that the cognitive activity of the I, via which it can reflect upon *itself*, cannot be understood as part of the causal world of appearances, and must therefore be part of the noumenal realm, the realm of the ‘unconditioned’. For Fichte the very fact of philosophy’s existence depends upon the free act of the I

which initiates the reflective questioning of its own activity by the I.

Schelling takes up the issues raised by Jacobi and Fichte in two texts of 1795: *Of the I as Principle of Philosophy or on the Unconditional in Human Knowledge*, and *Philosophical Letters on Dogmatism and Criticism*. In a move which prefigures aspects of Heidegger's questioning of the notion of being, he reinterprets Kant's question as to the condition of possibility of synthetic judgements a priori as a question about why there is a realm of judgements, a manifest world requiring syntheses by the subject for knowledge to be produced, at all. In *Of the I* Schelling puts Kant's question in Fichtean terms: 'how is it that the absolute I goes out of itself and opposes a Not-I to itself?'. He maintains that the condition of knowledge, the 'positing' by the I of that which is opposed to it, must have a different status from the determined realm which it posits: 'nothing can be posited by itself as a thing, i.e. an absolute/unconditioned thing (*unbedingtes Ding*) is a contradiction'. However, his key worry about Fichte's position already becomes apparent in the *Philosophical Letters*, where he drops the Fichtean terminology: '*How is it that I step at all out of the absolute and move towards something opposed (auf ein Entgegengesetztes)?*'. The problem Schelling confronts was identified by his friend Hölderlin, in the light of Jacobi's formulation of the problem of the 'unconditioned'. Fichte wished to understand the absolute as an I in order to avoid the problem of nature 'in itself' which creates Kantian dualism. For something to be an I, though, it must be conscious of an other, and thus in a relationship to that other. The overall structure of the relationship could not, therefore, be described from only one side of that relationship. Hölderlin argued that one has to understand the structure of the relationship of subject to object in consciousness as grounded in 'a whole of which subject and object are the parts', which he termed 'being'. This idea will be vital to Schelling at various times in his philosophy.

In the 1790s, then, Schelling is seeking a way of coming to terms with the ground of the subject's relationship to the object world. His aim is to avoid the fatalist consequences of Spinoza's system by taking on key aspects of Kant's and Fichte's transcendental philosophy, and yet not to fall into the trap Hölderlin identified in Fichte's conception of an absolute I. In his *Naturphilosophie* (philosophy of nature), which emerges in 1797 and develops in the succeeding years, and in the *System of Transcendental Idealism* of 1800, Schelling wavers between a Spinozist and a Fichtean approach to the 'unconditioned'. In the *Naturphilosophie* the Kantian division between appearing nature and nature in itself is seen as resulting from the fact that the nature theorised in cognitive judgements is objectified in opposition to the knowing subject. This objectification, the result of the natural sciences' search for fixed laws, fails to account for the living dynamic forces in nature, including those in our own organism, with which Kant himself became concerned in the third *Critique* and other late work, and which had played a role in Leibniz's account of nature. Nature in itself is thought of by Schelling as a 'productivity': 'As the object [*qua* 'conditioned condition'] is never absolute/unconditioned (*unbedingt*) then something per se non-objective must be posited in nature; this absolutely non-objective postulate is precisely the original productivity of nature'. The Kantian dualism between things in themselves and appearances is a result of the fact that the productivity can never appear as itself and can only appear in the form of 'products', which are the productivity 'inhibiting' itself. The products are never complete in themselves: they are like the eddies in a stream, which temporarily keep their shape via the resistance of the movement of the fluid to itself that creates them, despite the changing material flowing through them.

Schelling next tries to use the insights of transcendental philosophy, while still avoiding Kant's dualism, to explain our knowledge of nature. The vital point is that things in themselves and 'representations' cannot be absolutely different because we know a world which exists independently of our will which can yet be affected by our will:

> one can push as many transitory materials as one wants, which become finer and finer, between mind and matter, but sometime the point must come where mind and matter are One, or where the great leap that we so long wished to avoid becomes inevitable.

The *Naturphilosophie* includes ourselves within nature, as part of an interrelated whole, which is structured in an ascending series of 'potentials' that contain a polar opposition within themselves. The model is a magnet, whose opposing poles are inseparable from each other, even though they are opposites. As productivity nature cannot be conceived of as an object, since it is the subject of all possible real 'predicates', of the 'eddies' of which transient, objective nature consists. However, nature's 'inhibiting' itself in order to become something determinate means that the 'principle of all explanation of nature' is 'universal duality', an inherent difference of subject and object which prevents nature ever finally reaching stasis. At the same time this difference of subject and object must be grounded in an identity which links them together, otherwise all the problems of dualism would just reappear. In a decisive move for German Idealism, Schelling parallels the idea of nature as an absolute producing subject, whose predicates are appearing objective nature, with the spontaneity of the thinking subject, which is the condition of the syntheses required for the constitution of objectivity, thus for the possibility of predication in judgements. The problem for Schelling lies in explicating how these two subjects relate to each other.

In the *System of Transcendental Idealism* Schelling goes back to Fichtean terminology, though he will soon abandon most of it. He endeavours to explain the emergence of the thinking subject from nature in terms of an 'absolute I' coming retrospectively to know itself in a 'history of self-consciousness' that forms the material of the system. The *System* recounts the history of which the transcendental subject is the result. A version of the model Schelling establishes will be adopted by Hegel in the *Phenomenology of Mind*. Schelling presents the process in terms of the initially undivided I splitting itself in order to articulate itself in the syntheses, the 'products', which constitute the world of knowable nature. The founding stages of this process, which bring the world of material nature into being, are 'unconscious'. These stages then lead to organic nature, and thence to consciousness and self-consciousness. Schelling claims, in the wake of Fichte, that the resistance of the noumenal realm to theoretical knowledge results from the fact that 'the [practical] act [of the absolute I] via which all limitation is posited, as condition of all consciousness, does not itself come to consciousness'. He prophetically attempts to articulate a theory which comes to terms with the idea that thought is driven by forces which are not finally transparent to it, of the kind later to become familiar in psychoanalysis. How, though, does one gain access by thought to what cannot be an object of consciousness? This access is crucial to the whole project because without it there can be no understanding of why the move from determined nature to the freedom of self-determining thinking takes place at all.

Schelling adopts the idea from the early Romantic thinkers Friedrich Schlegel and Novalis, whom he

knew in Jena at this time, that art is the route to an understanding of what cannot appear as an object of knowledge. Philosophy cannot represent nature in itself because access to the sphere of the unconscious must be via what appears to consciousness in the realm of theoretical knowledge. The work of art is evidently an empirical, appearing object like any other, but if it is not more than what it is *qua* determinable object it cannot be a work of art, because this requires both the free judgement of the subject and the object's conveying of something beyond its objective nature. Although the *System*'s own very existence depends upon the transition from theoretical to practical philosophy, which requires the breaking-off of Jacobi's chain of 'conditions' by something unconditioned, Schelling is concerned to understand how the highest insight must be into reality as a product of the interrelation of both the 'conscious' and the 'unconscious'. Reality is not, therefore, essentially captured by a re-presentation of the objective by the subjective. Whereas in the *System* nature begins unconsciously and ends in conscious philosophical and scientific knowledge, in the art work: 'the I is conscious according to the production, unconscious with regard to the product'. The product cannot be understood via the intentions of its producer, as this would mean that it became a 'conditioned' object, something produced in terms of a pre-existing rule, and would therefore lack what makes mere craft into art. Art is, then, 'the only true and eternal organ and document of philosophy, which always and continuously documents what philosophy cannot represent externally'. The particular sciences can only follow the chain of conditions, via the principle of sufficient reason, and must determine any object via its place in that chain, a process which has no necessary end. The art object, on the other hand, manifests what cannot be understood in terms of its knowable conditions, because an account of the materials of which it is made or of its status as object in the world does not constitute it as art. Art shows what cannot be said. Philosophy cannot positively represent the absolute because 'conscious' thinking operates from the position where the 'absolute identity' of the subjective and the objective has always already been lost in the emergence of consciousness.

Although Schelling's early work did not fully satisfy either himself, or anybody else, it manages to address, in a cogent and illuminating fashion, a great deal of topics which affect subsequent philosophy. The model presented in the *System* impresses not least because, at the same time as establishing the notion of the history of self-consciousness that would be decisive for Hegel, it offers, in a manner which goes beyond its sources in Fichte, a model of the relationship between the subject and its conceptually inaccessible motivating forces which would affect significant parts of nineteenth century thought from Schopenhauer, to Nietzsche, to Freud.

3. Identity Philosophy

Although the period of Schelling's 'identity philosophy' is usually dated from the 1801 *Presentation of My System of Philosophy* until sometime before the 1809 *On the Essence of Human Freedom*, the project of that philosophy can be said to be carried on in differing ways throughout his work. The identity philosophy derives from Schelling's conviction that the self-conscious I must be seen as a result, rather than as the originating act it is in Fichte, and thus that the I cannot be seen as the generative matrix of the whole system. This takes him more in the direction of Spinoza, but the problem is still that of articulating the relationship between the I and the world of material nature, without either reverting to Kantian

dualism or failing to explain how a purely objective nature could give rise to subjectivity.

Schelling's mature identity philosophy, which is contained in the *System of the Whole of Philosophy and of Naturphilosophie in Particular*, written in Würzburg in 1804, and in other texts between 1804 and 1807, breaks with the model of truth as correspondence. It does so because:

> It is clear that in every explanation of the truth as a correspondence (*Übereinstimmung*) of subjectivity and objectivity in knowledge, both, subject and object, are already presupposed as separate, for only what is different can agree, what is not different is in itself one.

The crucial problem is how to explain the *link* between the subject and object world that makes judgements possible, and this cannot be achieved in terms of how a subject can have thoughts which correspond to an object essentially separate from it. For there to be judgements at all what is split and then synthesised in the judgement must, Schelling contends, in some way already be the same. This has often been understood as leading Schelling to a philosophy in which, as Hegel puts it in the *Phenomenology*, the absolute is the 'night in which all cows are black', because it swallows all differentiated knowledge in the assertion that everything is ultimately the same, namely an absolute which excludes all relativity from itself and thus becomes inarticulable. This is not a valid interpretation of Schelling's argument, and Hegel's remark seems, incidentally, not to have been directed against Schelling anyway.

In order to try to get over the problem in monism of how the One is also the many, Schelling, following the idea outlined above from Hölderlin, introduces a notion of 'transitive' being, which links mind and matter as predicates of itself. Schelling explains this 'transitivity' via the metaphor of the earth:

> you recognise its [the earth's] true essence only in the link by which it eternally posits its unity as the multiplicity of its things and again posits this multiplicity as its unity. You also do not imagine that, apart from this infinity of things which are in it, there is another earth which is the unity of these things, rather *the same* which is the multiplicity is also unity, and *what* the unity is, is also the multiplicity, and this necessary and indissoluble One of unity and multiplicity in it is what you call its existence (...) Existence is the link of a being (*Wesen*) as One, with itself as a multiplicity.

'Absolute identity' is, then, the *link* of the two aspects of being, which, on the one hand, is the *uni*verse, and, on the other, is the changing *multi*plicity which the knowable universe also is. Schelling insists now that 'The *I* think, *I* am, is, since Descartes, the basic mistake of all knowledge; thinking is not my thinking, and being is not my being, for everything is only of God or the totality', so the I is 'affirmed' as a predicate of the being by which it is preceded. In consequence he already begins to move away, albeit inconsistently, from the German Idealist model in which the intelligibility of being is regarded as a result of its having an essentially mind-like structure.

Schelling is led to this view by his understanding of the changing and relative status of theoretical knowledge. It is the inherent incompleteness of all finite determinations which reveals the nature of the absolute. His description of time makes clear what he means: ‘time is itself nothing but *the totality appearing in opposition to the particular life of things*’, so that the totality ‘posits or intuits itself, by not positing, not intuiting the particular’. The particular is determined in judgements, but the truth of claims about the totality cannot be proven because judgements are necessarily conditioned, whereas the totality is not. Given the relative status of the particular there must, though, be a ground which enables us to be *aware* of that relativity, and this ground must have a different status from the knowable world of finite particulars. At the same time, if the ground were wholly different from the world of relative particulars the problems of dualism would recur. As such the absolute *is* the finite, but we do not *know* this in the manner we know the finite. Without the *presupposition* of ‘absolute identity’, therefore, the evident relativity of particular knowledge becomes inexplicable, since there would be no reason to claim that a revised judgement is predicated of the same world as the preceding -- now false -- judgement.

Schelling summarises his theory of identity as follows:

> for being, actual, real being is precisely self-disclosure/revelation (*Selbstoffenbarung*). If it is to be as One then it must disclose/reveal itself in itself; but it does not disclose/reveal itself in itself if it is not an other in itself, and is *in* this other the One for itself, thus if it is not absolutely the living link of itself and an other.

The link between the ‘real’ and the ‘ideal’ cannot be regarded as a causal link. Although there cannot be mental events without physical events, the former cannot be reduced to being the causal results of the latter: ‘For real and ideal are only different views of one and the same substance’. Schelling wavers at this time between a ‘reflexive’ position of the kind which Hegel will soon try to articulate, in which, in Schelling’s terms, ‘the sameness of the subjective and the objective is made the same as itself, knows itself, and is the subject and object of itself’, in the ‘identity of identity and difference’, and the sense that this position cannot finally circumscribe the structure of the absolute. The structure of reflection, where each aspect reflects itself and then is reflected in the other, upon which this account of the identity of subject and object relies, must be grounded in a being which carries it:

> reflection (...) only knows the universal and the particular as two relative negations, the universal as relative negation of the particular, which is, as such, without reality, the particular, on the other hand, as a relative negation of the universal.(...) something independent of the concept must be added to posit the substance as such.

Without this independent basis subject and object would merely be, as Schelling thinks they are in Fichte, relative negations of each other, leading to a circle ‘inside which a nothing gains reality by the relation to another nothing’. Schelling prophetically distinguishes between the cognitive -- reflexive -- ground of finite knowledge and the real -- non-reflexive -- ground that sustains the movement of negation from one finite determination to another. As a two-sided relationship reflection alone always entails the problem that the subject and the object in a case of reflection can only be *known* to be the same via that which cannot appear in the reflection. If I am to recognise myself *as* myself in a mirror, rather than see a

random object in the world, I must *already* be familiar with myself *before* the reflection, in a way which is not part of the reflection. This means a complete system based on reflection is impossible, because, in order for the system to be grounded, it must presuppose as external to itself what it claims is part of itself. Schelling will, in his philosophy from the 1820s onwards, raise this objection against Hegel's system of 'absolute reflection'.

Schelling's own dissatisfaction with his early versions of identity theory derives from his rejection of Spinozism. Spinoza regards the move from God to the world of 'conditions' as a logical consequence of the nature of God. Schelling becomes convinced that such a theory gives no reason why the absolute, the 'unconditioned', should manifest itself in a world of negative 'conditions' at all. Schelling is therefore confronted with explaining why there is a transition from the absolute to the finite world. In *Philosophy and Religion*, of 1804, he claims, like Jacobi, that there is no way of mediating between conditioned and unconditioned, and already makes the distinction between 'negative' and 'positive' philosophy, which will form the heart of his late work. Explicating the structure of the finite world leads to 'negative philosophy, but much has already been gained by the fact that the negative, the realm of nothingness, has been separated by a sharp limit from the realm of reality and of what alone is positive'. The question which comes to concern Schelling is how philosophy can come to terms with a ground which cannot be regarded as the rational explanation of the finite world.

4. The 'Ages of the World'

Schelling's work from his middle period (1809-1827) is usually referred to as the philosophy of the *Ages of the World* (WA = *Weltalter*), after the title of the unfinished work of that name he worked on in the period 1809-1827. The work characteristic of this period begins with the 1809 *On the Essence of Human Freedom* (FS = *Freiheitsschrift*) (written in Stuttgart). The WA philosophy is an attempt to explain the emergence of an intelligible world at the same time as coming to terms with mind's inextricable relation to matter. The initial concern is to avoid Spinoza's fatalism, which renders the human freedom to do good *and* evil incomprehensible. Schelling's crucial objection is to the idea that evil should be understood as merely another form of negativity which can be comprehended by insight into the inherent lack in all finite parts of a totality, rather than as a positive fact relating to the nature of human freedom. He now sees the fundamental contradictions of the *Naturphilosophie* in terms of the relationship of the intelligibility of nature and ourselves to a ground without which there could be no intelligibility, but which is not the explicable cause of intelligibility. In an attempt to get to grips with the problem of the ground of the finite world Schelling introduces a Kant-derived conception of 'willing' in the FS which will be influential for Schopenhauer's conception of the 'Will': 'In the last and highest instance there is no other being but willing. Willing is primal being, and all the predicates of primal being only fit willing: groundlessness, eternity, being independent of time, self-affirmation'. Schelling now establishes a more conflictual version of the structure of the identity philosophy. The 'ground' is 'groundless' -- in the sense of 'uncaused' -- and it must be understood in terms of freedom if a Spinozist determinism is to be avoided. This means there cannot be an explanation of the finite world, because that would entail taking the ground as a cause and thus rendering freedom non-existent.

At the same time Schelling insists there must be that against which freedom can be manifest -- a being which is not free and is therefore necessitated -- for it to be meaningful freedom at all. The theory is based on the antagonisms between opposing forces which constitute the ‘ages of the world’, the past, present, and future. He argues that the world whose origins the WA wishes to understand must entail the *same* conflicting forces which still act, though not necessarily in the same *form*, in this world, of which the mind is an aspect: ‘Poured from the source of things and the same as the source, the human soul has a co-knowledge/con-science (*Mitwissenschaft*) of creation’. Schelling suggests that there are two principles in us: ‘an unconscious, dark principle and a conscious principle’, which must yet in some way be identical. The same structure applies to what Schelling means by ‘God’. At this point his account of the ground is not consistent, but this inconsistency points to the essential issue Schelling is trying to understand, namely whether philosophy can give a rational account of the fact of the manifest world. As that which makes the world intelligible, God relates to the ground in such a way that the ‘real’, which takes the form of material nature, is ‘in God’ but ‘is not God seen absolutely, i.e. insofar as He exists; for it is only the ground of His existence, it is *nature* in God; an essence which is inseparable from God, but different from Him’. The point is that God would be meaningless if there were not that which He transcends: without opposition, Schelling argues, there is no life and no sense of development, which are the highest aspects of reality. The aim of the move away from Spinoza is to avoid the sense of a world complete in itself which would render freedom illusory because freedom’s goal would already be determined as part of the totality. Schelling starts to confront the idea that the reconciliation of freedom and necessity that had been sought by Kant in the acknowledgement of the necessity of the law, and which was the aim of German Idealism’s attempt to reconcile mind and nature, might be intrinsically unattainable.

Wolfram Hogrebe has convincingly claimed that the WA philosophy is an ontological theory of predication. Being, as initially One and enclosed within itself, is not manifest, and has no reason to be manifest. Hogrebe terms this ‘pronominal being’. The *same* being must also, given that there is now a manifest world, be ‘predicative being’ (ibid.), which ‘flows out, spreads, gives itself’. The contradiction between the two kinds of being is only apparent. Schelling maintains, in line with the identity philosophy, that the ‘properly understood law of contradiction really only says that the same cannot be *as the same* something and also the opposite thereof, but this does not prevent the same, which is A, being able, as an other, to be not A’. One aspect of being, the dark force, which he sometimes terms ‘gravity’, is contractive, the other expansive, which he terms ‘light’. Dynamic processes are the result of the interchange between these ultimately identical forces: if they were wholly separate there would either be no manifest universe or the universe would dissipate at infinite speed. If something is to be *as* something it must both be, in the positive sense in which everything else is, which makes it indeterminately positive, pronominal, and it must have a relationship to what it is not, in order to be determinate, which brings it into the realm of predication by taking it beyond itself. In the WA the One comes into contradiction with itself and the two forces constantly vie with each other. Differences must, however, be grounded in unity, as otherwise they could not be *manifest* at all as differences. The ground is now increasingly regarded as the source of the transitory nature of everything particular, and less and less as the source of tranquil insight into how we can be reconciled to finite existence. The mood of the WA is summed up in Schelling’s reference to the ‘veil of melancholy which is spread over the whole of nature, the deep indestructible melancholy of all life’. The source of this melancholy is that everything finite must ‘go to

ground' and that we are *aware* of this.

The abandonment of his residual Spinozism leads Schelling to a growing concern with the tensions which result from contradictions that are also embodied in human beings. The ages of the world are constituted by the development of forms and structures in the material and the mental world. This development depends upon the expanding force's interaction with the contracting force's slowing of any expansion, which allows transient but determinate forms to develop. This process also gives rise to language, which Schelling regards as the model for the development of the whole world because it manifests how expansion and the release of tension can lead to intelligibility, rather than mere dissipation:

> It seems universal that every creature which cannot contain itself or draw itself together in its own fullness, draws itself together outside itself, whence e.g. the elevated miracle of the formation of the word in the mouth belongs, which is a true creation of the full inside when it can no longer remain in itself.

Language as 'contracted' material signifier, and 'expanding' ideal meaning repeats the basic structure of the WA, and Schelling insists that, like the material world without the 'ideal' capacity for expansion, language can become 'congealed'. This interaction between what is contained in itself and what draws something beyond itself is also what gives rise to consciousness, and thus to an inherent tension within consciousness, which can only be itself by its relation to an other. Hegel uses a related model of subjectivity, but Schelling will come to reject Hegel's model for its conjuring away of the ultimately irresolvable tension in all subjectivity. Schelling's later philosophy will present a subject whose origin prevents it from ever achieving the 'self-presence' Hegel thinks he can explicate via the completed structure of 'self-reflection' in the other. Schelling's WA philosophy is never completed: its Idealist aim of systematically unifying subject and object by comprehending the real development of history from the very origins of being founders on problems concerning the relationship between philosophical system and historical contingency which do not admit of solutions. Furthermore, the structures he develops lead him to ideas which take him beyond Idealism and make him one of the crucial precursors of existential and other non-Idealist forms of modern philosophy.

5. Positive and Negative Philosophy, and the Critique of Hegel

Schelling has usually been understood as providing the transitional 'objective idealist' link between Fichte and Hegel. By regarding Hegel's system as the culmination of German Idealism this interpretation fails to do justice to Schelling's real philosophical insights. Many of these insights, particularly in the later philosophy (1827-1854), directly and indirectly influenced the ideas of thinkers, like Feuerbach, Kierkegaard, Nietzsche, and Heidegger, who were critical of Hegel's claim to articulate a complete philosophical system.

The differences between Hegel and Schelling derive from their respective approaches to understanding

the absolute. For Hegel the absolute is the *result* of the self-cancellation of the finite. It can therefore be presented in the form of the successive overcoming of finite determinations, the 'negation of the negation', in a system whose end comprehends its beginning. For Hegel the result becomes known when the beginning moves from being 'in itself' to being 'for itself' at the end of the system, thus in a process in which it reflects itself to itself. Schelling already becomes publicly critical of Hegel while working on a later version of the WA philosophy in Erlangen in the 1820s, but makes his criticisms fully public in lectures given in Munich in the 1830s, and in the 1840s and 1850s as professor in Berlin. The aim of the Idealist systems was for thought to reflect what it is not -- being -- as really itself, even as it appears not to be itself, thereby avoiding Kant's dualism. The issue between Schelling and Hegel is whether the grounding of reason by itself is not in fact a sort of philosophical narcissism, in which reason admires its reflection in being without being able fully to articulate its relationship to that reflection. Like Hegel, Schelling argues that it is not the particular manifestation of knowledge which tells me the truth about the world, but rather the necessity of moving from one piece of knowledge to the next. However, a logical reconstruction of the process of knowledge can, for Schelling, only be a reflection of thought by itself. The real process cannot be described in philosophy, because the cognitive ground of knowledge and the real ground, although they are inseparable from each other, cannot be shown to *reflect* each other.

Dieter Henrich characterises Hegel's conception of the absolute as follows: 'The absolute is the finite to the extent to which the finite is nothing at all but negative relation to itself'. Hegel's system depends upon showing how each particular way of conceiving of the world has an internal contradiction. This necessarily leads thought to more comprehensive ways of grasping the world, until the point where there can be no more comprehensive way because there is no longer any contradiction to give rise to it. The very fact of the finite limitations of empirical thought therefore becomes what gives rise to the infinite, which, in Hegel's terms, is thought that is bounded by itself and by nothing else.

Schelling accepts such a conception, to which he substantially contributed in his early philosophy, as the way to construct a 'negative' system of philosophy, because it explains the logic of change, once there is a world to be explained. The conception does not, though, explain why there is a developing world at all, but merely reconstructs in thought the necessary structure of development on the basis of necessities in thought. Schelling's own attempt at explaining the world's ontological and historical facticity will lead him to a 'philosophical theology' which traces the development of mythology and then of Christian revelation in his *Philosophy of Mythology* and *Philosophy of Revelation*, which, like all his substantial works after 1811, are not published in his lifetime. The failure of his philosophical theology does not, though, necessarily invalidate his philosophical arguments against Hegel. His alternative to the 'common mistake of every philosophy that has existed up to now' -- the 'merely logical relationship of God to the world' (ibid.) -- Schelling terms 'positive philosophy'. The 'merely logical relationship' entails a reflexivity, in which the world necessarily follows from the nature of God, and God and the world are therefore the 'other of themselves'. Hegel's system tries to obviate the facticity of the world by understanding reason as the world's immanent self-articulation. Schelling, in contrast, insists that human reason cannot explain its *own* existence, and therefore cannot encompass itself and its other within a system of philosophy. We cannot, he maintains, make sense of the manifest world by beginning with reason, but must instead begin with the contingency of being and try to make sense of it with the reason which is only one aspect of it and which cannot be explained in terms of its being a reflection of the true

nature of being.

Schelling contends that the identity of thought and being cannot be articulated *within* thought, because thought must *presuppose* that they are identical in a way which thought, as one side of a relation, cannot comprehend. By redefining the ‘concept’ in such a way that it is always already both subject and object, Hegel aims to avoid any presuppositions on either the subject or the object side, allowing the system to complete itself as the ‘self-determination of the concept’. Schelling presents the basic alternative as follows:

> For either the concept would have to go first, and being would have to be the consequence of the concept, which would mean it was no longer absolute being; or the concept is the consequence of being, then we must begin with being without the concept.

Hegel attempts to merge concept and being by making being part of a structure of self-reflection, rather than the basis of the interrelation between subject and object. He invalidly assumes that ‘essence’, which is one side of the relationship between being and essence, can articulate its identity with the other side in the ‘concept’, because the other side is revealed as being ‘nothing’ until it has entered into a relationship which makes it determinate as a knowable moment of the whole process.

The problem which Hegel does not overcome is that this identity cannot be *known*, because, as Schelling claims of his concept of being, ‘existing is not here the consequence of the concept or of essence, but rather existence is here itself the concept and itself the essence’. The problem of reflection cannot be overcome in Hegel’s manner: identifying one’s reflection in a mirror as oneself (understood now as a metaphor for essence) entails, as we saw above, a prior non-reflexive moment if one is to know that the reflection *is* oneself, rather than a random reflected object. How far Schelling moves from any reflexive version of identity philosophy is evident in the following from the *Introduction to the Philosophy of Revelation or Foundation of the Positive Philosophy* of 1842-3:

> our self-consciousness is not at all the consciousness of that nature which has passed through everything, it is precisely just *our* consciousness (...) for the consciousness of man is not = the consciousness of nature (...) Far from man and his activity making the world comprehensible, man himself is that which is most incomprehensible.

Schelling refuses to allow that reason can confirm its status via its reflection in being:

> what we call the world, which is *so completely contingent* both as a whole and in its parts, cannot possibly be the impression of something which has arisen by the *necessity of reason* (...) it contains a *preponderant* mass of *unreason*.

Schelling is, then, one of the first philosophers seriously to begin the destruction of the model of metaphysics based on the idea of representation, a destruction which can be seen as one of the key aspects of modern philosophy from Heidegger to the later Wittgenstein and beyond. He is, at the same

time, unlike some of his successors, committed to an account of human reason which does not assume that reason's incapacity to ground itself should lead to the Nietzschean abandonment of rationality. This is one of the respects in which Schelling has again become part of contemporary debate, where the need to seek means of legitimation which do not rely on the notion of a rationality inherent in the world remains a major challenge. Schelling's account of mind and world, particularly his insistence on the need not to limit our conception of nature to what is accessible to objectifying forms, is, in the light of the ecological crisis, proving to be more durable than his reception might until recently have suggested.

Bibliography

Editions of Schelling

- *Friedrich Wilhelm Joseph Schelling's Sämmtliche Werke*, ed. K.F.A. Schelling, I Abtheilung Vols. 1-10, II Abtheilung Vols. 1-4, Stuttgart: Cotta, 1856-61. An easily accessible substantial selection of the complete works has been published, ed. M. Frank, as *Friedrich Wilhelm Joseph von Schelling, Ausgewählte Schriften*, 6 Vols., Frankfurt: Suhrkamp 1985.
- *Die Weltalter*, ed. M. Schröter, Munich: Biederstein 1946, which has other versions than the version from 1813 printed in the *Sämmtliche Werke*.
- The *Historisch-kritische Ausgabe, im Auftrag der Schelling-Kommission der Bayerischen Akademie der Wissenschaften*, edited by H. M. Baumgartner, W.G. Jacobs, H. Krings, Stuttgart 1976- is still a long way from completion, but will become the new standard edition.
- *Über die Möglichkeit einer Form der Philosophie überhaupt* (1794) (On the Possibility of an Absolute Form of Philosophy), *Vom Ich als Prinzip der Philosophie oder über das Unbedingte im menschlichen Wissen* (1795) (Of the I as the Principle of Philosophy or on the Unconditional in Human Knowledge), *Philosophische Briefe über Dogmatismus und Kriticismus* (1795) (Philosophical Letters on Dogmatism and Criticism) in *The Unconditional in Human Knowledge*: Four early essays 1794-6 (1980) translation and commentary by F. Marti, Lewisburg: Bucknell University Press.
- *Abhandlungen zur Erläuterung des Idealismus der Wissenschaftslehre* (1796-7) (Essays in Explanation of the Idealism of the Doctrine of Science).
- *Ideen zu einer Philosophie der Natur als Einleitung in das Studium dieser Wissenschaft* (1797) *Ideas for a Philosophy of Nature: as Introduction to the Study of this Science* (1988) translated by E.E. Harris and P. Heath, introduction R. Stern, Cambridge: Cambridge University Press.
- *Erster Entwurf eines Systems der Naturphilosophie* (1799) (First Plan of a System of the Philosophy of Nature).

Søren Kierkegaard

Søren Aabye Kierkegaard (b.1813, d. 1855) was a profound and prolific writer in the Danish "golden age" of intellectual and artistic activity. His work crosses the boundaries of philosophy, theology, psychology, literary criticism, devotional literature and fiction. Kierkegaard brought this potent mixture of discourses to bear as social critique and for the purpose of renewing Christian faith within Christendom. At the same time he made many original conceptual contributions to each of the disciplines he employed. He is known as the "father of existentialism", but at least as important are his critiques of Hegel and of the German romantics, his contributions to the development of modernism, his literary experimentation, his vivid re-presentation of biblical figures to bring out their modern relevance, his invention of key concepts which have been explored and redeployed by thinkers ever since, his interventions in contemporary Danish church politics, and his fervent attempts to analyse and revitalise Christian faith. Kierkegaard burned with the passion of a religious poet, was armed with extraordinary dialectical talent, and drew on vast resources of erudition.

Kierkegaard's Life

Kierkegaard led a somewhat uneventful life. He rarely left his hometown of Copenhagen, and travelled abroad only three times -- to Berlin. His prime recreational activities were attending the theatre, walking the streets of Copenhagen to chat with ordinary people, and taking brief carriage jaunts into the surrounding countryside. He was educated at a prestigious boys' school (*Borgedydskolen*), then attended

Copenhagen University where he studied philosophy and theology. His teachers at the university included F.C. Sibbern, Poul Martin Møller, and H.L. Martensen.

Sibbern and Møller were both philosophers who also wrote fiction. The latter in particular had a great influence on Kierkegaard's philosophico-literary development. Martensen also had a profound effect on Kierkegaard, but largely in a negative manner. Martensen was a champion of Hegelianism, and when he became Bishop Primate of the Danish People's Church, Kierkegaard published a vitriolic attack on Martensen's theological views. Kierkegaard's brother Peter, on the other hand, was an adherent of Martensen and himself became a bishop in the church.

Another very important figure in Kierkegaard's life was J.L. Heiberg, the doyen of Copenhagen's literati. Heiberg, more than any other person, was responsible for introducing Hegelianism into Denmark. Kierkegaard spent a good deal of energy trying to break into the Heiberg literary circle, but desisted once he had found his own voice in *The Concept of Irony*. Kierkegaard's first major publication, *From the Papers of One Still Living*, is largely an attempt to articulate a Heibergian aesthetics - which is a modified version of Hegel's aesthetics. In *From the Papers of One Still Living*, which is a critical review of Hans Christian Andersen's novel *Only A Fiddler*, Kierkegaard attacks Andersen for lacking life-development (*Livs-Udvikling*) and a life-view (*Livs-Anskuelse*) both of which Kierkegaard deemed necessary for someone to be a genuine novelist (*Romandigter*).

Kierkegaard's life is more relevant to his work than is the case for many writers. Much of the thrust of his critique of Hegelianism is that its system of thought is abstracted from the everyday lives of its proponents. This existential critique consists in demonstrating how the life and work of a philosopher contradict one another. Kierkegaard derived this form of critique from the Greek notion of judging philosophers by their lives rather than simply by their intellectual artefacts. The Christian ideal, according to Kierkegaard, is even more exacting since the totality of an individual's existence is the artefact on the basis of which s/he is judged by God for h/er eternal validity. Of course a writer's work is an important part of h/er existence, but for the purpose of judgement we should focus on the whole life not just on one part.

In a less abstract manner, an understanding of Kierkegaard's biography is important for an understanding of his writing because his life was the source of many of the preoccupations and repetitions within his *oeuvre*. Because of his existentialist orientation, most of his interventions in contemporary theory do double duty as means of working through events from his own life. In particular Kierkegaard's relations to his mother, his father, and his fiancée Regine Olsen pervade his work.

Kierkegaard's relation to his mother is the least frequently commented upon since it is invisible in his work. His mother does not rate a direct mention in his published works, or in his diaries -- not even on the day she died. However, for a writer who places so much emphasis on indirect communication, and on the semiotics of invisibility, we should regard this absence as significant. Johannes Climacus in *Concluding Unscientific Postscript* remarks, "... how deceptive then, that an omnipresent being should be recognisable precisely by being invisible." Kierkegaard's mother, who was not well educated, is

represented in his writings by the mother-tongue (Danish). Kierkegaard was deeply enamoured of the Danish language and worked throughout his writings to assert the strengths of his mother-tongue over the invasive, imperialistic influences of Latin and German. With respect to the former, Kierkegaard had to petition the king to be allowed to write his philosophy dissertation *On the Concept of Irony with constant reference to Socrates* in Danish. Even though permission was granted he was still required to defend his dissertation publicly in Latin. Latin had been the pan-European language of science and scholarship. In Denmark, in Kierkegaard's time, German language and culture were at least as dominant as Latin in the production of knowledge. In defiance of this, Kierkegaard revelled in his mother-tongue and created some of the most beautifully poetic prose in the Danish language -- including a paeon to his mother-tongue in *Stages On Life's Way*. In *Repetition* Constantin Constantius congratulates the Danish language on providing the word for an important new philosophical concept, viz. *Gjentagelse* (repetition), to replace the foreign word "mediation". In general, the Danish language is Kierkegaard's umbilical attachment to the mother whereas Latin and German represent the law of the father, especially when employed in systematic scholarship (*Videnskab*).

The influence of Kierkegaard's father on his work has been frequently noted. Not only did Kierkegaard inherit his father's melancholy, his sense of guilt and anxiety, and his pietistic emphasis on the dour aspects of Christian faith, but he also inherited his talents for philosophical argument and creative imagination. In addition Kierkegaard inherited enough of his father's wealth to allow him to pursue his life as a freelance writer. The themes of sacrificial father/son relationships, of inherited sin, of the burden of history, and of the centrality of the "individual, human existence relationship, the old text, well known, handed down from the fathers" (*Postscript*) are repeated many times in Kierkegaard's oeuvre. The father's sense of guilt was so great (for having cursed God? for having impregnated Kierkegaard's mother out of wedlock?) that he thought God would punish him by taking the lives of all seven of his children before they reached the age of 34 (the age of Jesus Christ at his crucifixion). This was born out for all but two of the children, Søren and his older brother Peter, both of whom were astonished to survive beyond that age. This may explain the sense of urgency that drove Kierkegaard to write so prolifically in the years leading up to his 34th birthday.

Kierkegaard's (broken) engagement to Regine Olsen has also been the focus of much scholarly attention. The theme of a young woman being the occasion for a young man to become "poeticized" recurs in Kierkegaard's writings, as does the theme of the sacrifice of worldly happiness for a higher (religious) purpose. Kierkegaard's infatuation with Regine, and the sublimated libidinal energy it lent to his poetic production, were crucial for setting his life course. The breaking of the engagement allowed Kierkegaard to devote himself monastically to his religious purpose, as well as to establish his outsider status (outside the norm of married bourgeois life). It also freed him from close personal entanglements with women, thereby leading him to objectify them as ideal creatures, and to reproduce the patriarchal values of his church and father.

Kierkegaard's Rhetoric

Kierkegaard's central problematic was *how to become a Christian in Christendom*. The task was most

difficult for the well-educated, since prevailing educational and cultural institutions tended to produce stereotyped members of "the crowd" rather than to allow individuals to discover their own unique identities. This problem was compounded by the fact that Denmark had recently and very rapidly been transformed from a feudal society into a capitalist society. Universal elementary education, large-scale migration from rural areas into cities, and greatly increased social mobility meant that the social structure changed from a rigidly hierarchical one to a relatively "horizontal" one. In this context it became increasingly difficult to "become who you are" for two reasons: (i) social identities were unusually fluid; and (ii) there was a proliferation of normalizing institutions which produced pseudo-individuals.

Given this problematic in this social context Kierkegaard perceived a need to invent a form of communication which would not produce stereotyped identities. On the contrary, he needed a form of rhetoric which would force people back onto their own resources, to take responsibility for their own existential choices, and to become who they are beyond their socially imposed identities. In this undertaking Kierkegaard was inspired by the figure of Socrates, whose incessant irony undermined all knowledge claims that were taken for granted or unreflectively inherited from traditional culture. In his dissertation *On the Concept of Irony with constant reference to Socrates* Kierkegaard argued that the historical Socrates used his irony in order to facilitate the birth of subjectivity in his interlocutors. Because they were constantly forced to abandon their pat answers to Socrates' annoying questions, they had to begin to think for themselves and to take individual responsibility for their claims about knowledge and value.

Kierkegaard sought to provide a similar service for his own contemporaries. He used irony, parody, satire, humor, and deconstructive techniques in order to make conventionally accepted forms of knowledge and value untenable. He was a gadfly -- constantly irritating his contemporaries with discomforting thoughts. He was also a midwife -- assisting at the birth of individual subjectivity by forcing his contemporaries to think for themselves. His art of communication became "the art of *taking away*" since he thought his audience suffered from too much knowledge rather than too little.

Hegelianism promised to make absolute knowledge available by virtue of a science of logic. Anyone with the capacity to follow the dialectical progression of the purportedly transparent concepts of Hegel's logic would have access to the mind of God (which for Hegel was equivalent to the logical structure of the universe). Kierkegaard thought this to be the hubristic attempt to build a new tower of Babel, or a *scala paradisi* -- a dialectical ladder by which humans can climb with ease up to heaven. Kierkegaard's strategy was to invert this dialectic by seeking to make everything more difficult. Instead of seeing scientific knowledge as the means of human redemption, he regarded it as the greatest obstacle to redemption. Instead of seeking to give people more knowledge he sought to take away what passed for knowledge. Instead of seeking to make God and Christian faith perfectly intelligible he sought to emphasize the absolute transcendence by God of all human categories. Instead of setting himself up as a religious authority, Kierkegaard used a vast array of textual devices to undermine his authority as an author and to place responsibility for the existential significance to be derived from his texts squarely on the reader.

Kierkegaard distanced himself from his texts by a variety of devices which served to problematize the

authorial voice for the reader. He used pseudonyms in many of his works (both overtly aesthetic ones and overtly religious ones). He partitioned the texts into prefaces, forewords, interludes, postscripts, appendices. He assigned the "authorship" of parts of texts to different pseudonyms, and invented further pseudonyms to be the editors or compilers of these pseudonymous writings. Sometimes Kierkegaard appended his name as author, sometimes as the person responsible for publication, sometimes not at all. Sometimes Kierkegaard would publish more than one book on the same day. These simultaneous books embodied strikingly contrasting perspectives. He also published whole *series* of works simultaneously, viz. the pseudonymous works on the one hand and on the other hand the *Edifying Discourses* published under his own name.

All of this play with narrative point of view, with contrasting works, and with contrasting internal partitions within individual works leaves the reader very disoriented. In combination with the incessant play of irony and Kierkegaard's predilection for paradox and semantic opacity, the text becomes a polished surface for the reader in which the prime meaning to be discerned is the reader's own reflection. Christian faith, for Kierkegaard, is not a matter of learning dogma by rote. It is a matter of the individual repeatedly renewing h/er passionate subjective relationship to an object which can never be known, but only believed in. This belief is offensive to reason, since it only exists in the face of the absurd (the paradox of the eternal, immortal, infinite God being incarnated in time as a finite mortal).

Kierkegaard's "method of indirect communication" was designed to sever the reliance of the reader on the authority of the author and on the received wisdom of the community. The reader was to be forced to take individual responsibility for knowing who s/he is and for knowing where s/he stands on the existential, ethical and religious issues raised in the texts.

Kierkegaard's "inverted Christian dialectic" was designed not to make the word of God easier to assimilate, but to establish more clearly the absolute distance that separates human beings from God. This was in order to emphasize that human beings are absolutely reliant on God's grace for salvation.

Kierkegaard's Aesthetics

Kierkegaard presents his pseudonymous authorship as a dialectical progression of existential stages. The first is the aesthetic, which gives way to the ethical, which gives way to the religious. The aesthetic stage of existence is characterized by the following: immersion in sensuous experience; valorization of possibility over actuality; egotism; fragmentation of the subject of experience; nihilistic wielding of irony and scepticism; and flight from boredom.

The figure of the aesthete in the first volume of *Either-Or* is an ironic portrayal of German romanticism, but it also draws on medieval characters as diverse as Don Juan, Ahasverus (the wandering Jew), and Faust. It finds its most sophisticated form in the author of "The Seducer's Diary", the final section of *Either-Or*. Johannes the seducer is a *reflective aesthete*, who gains sensuous delight not so much from the act of seduction but from engineering the possibility of seduction. His real aim is the manipulation of people and situations in ways which generate interesting reflections in his own voyeuristic mind. The

aesthetic perspective transforms quotidian dullness into a richly poetic world by whatever means it can. Sometimes the reflective aesthete will inject interest into a book by reading only the last third, or into a conversation by provoking a bore into an apoplectic fit so that he can see a bead of sweat form between the bore's eyes and run down his nose. That is, the aesthete uses artifice, arbitrariness, irony, and wilful imagination to recreate the world in his own image. The prime motivation for the aesthete is the transformation of the boring into the interesting.

This type of aestheticism is criticized from the point of view of ethics. It is seen to be emptily self-serving and escapist. It is a despairing means of avoiding commitment and responsibility. It fails to acknowledge one's social debt and communal existence. And it is self-deceiving insofar as it substitutes fantasies for actual states of affairs.

But Kierkegaard did not want to abandon aesthetics altogether in favor of the ethical and the religious. A key concept in the Hegelian dialectic, which Kierkegaard's pseudonymous authorship parodies, is *Aufhebung* (sublation). In Hegel's dialectic, when contradictory positions are reconciled in a higher unity (synthesis) they are both annulled and preserved (*aufgehoben*). Similarly with Kierkegaard's pseudo-dialectic: the aesthetic and the ethical are both annulled and preserved in their synthesis in the religious stage. As far as the aesthetic stage of existence is concerned what is preserved in the higher religious stage is the sense of infinite possibility made available through the imagination. But this no longer excludes what is actual. Nor is it employed for egotistic ends. Aesthetic irony is transformed into religious humor, and the aesthetic *transfiguration* of the actual world into the ideal is transformed into the religious *transubstantiation* of the finite world into an actual reconciliation with the infinite.

But the dialectic of the pseudonymous authorship never quite reaches the truly religious. We stop short at the *representation* of the religious by a self-confessed humorist (Johannes Climacus) in a medium which, according to Climacus's own account, necessarily alienates the reader from true (Christian) faith. For faith is a matter of lived experience, of constant striving within an individual's existence. According to Climacus's metaphysics, the world is divided dualistically into the actual and the ideal. Language (and all other media of representation) belong to the realm of the ideal. No matter how eloquent or evocative language is it can never *be* the actual. Therefore, any representation of faith is always suspended in the realm of ideality and can never *be* actual faith.

So the whole dialectic of the pseudonymous authorship is recuperated by the aesthetic by virtue of its medium of representation. In fact Johannes Climacus acknowledges this implicitly when at the end of *Concluding Unscientific Postscript* he *revokes* everything he has said, with the important rider that to say something then to revoke it is not the same as never having said it in the first place. His presentation of religious faith in an aesthetic medium at least provides an opportunity for his readers to make their own leap of faith, by appropriating with inward passion the paradoxical religion of Christianity into their own lives.

As a poet of the religious Kierkegaard was always preoccupied with aesthetics. In fact, contrary to popular misconceptions of Kierkegaard which represent him as becoming increasingly hostile to poetry,

he referred increasingly to himself as a poet in his later years (all but one of over ninety references to himself as a poet in his journals date from after 1847). Kierkegaard never claimed to write with religious authority, as an apostle. His works represent both less religiously enlightened and more religiously enlightened positions than he thought he had attained in his own existence. Such representations were only possible in an aesthetic medium of imagined possibilities like poetry.

Kierkegaard's Ethics

Like the terms "aesthetic" and "religious", the term "ethics" in Kierkegaard's work has more than one meaning. It is used to denote both: (i) a limited existential sphere, or stage, which is superseded by the higher stage of the religious life; and (ii) an aspect of life which is retained even within the religious life. In the first sense "ethics" is synonymous with the Hegelian notion of *Sittlichkeit*, or customary mores. In this sense "ethics" represents "the universal", or more accurately the prevailing social norms. The social norms are seen to be the highest court of appeal for judging human affairs -- nothing outranks them for this sort of ethicist. Even human sacrifice is justified in terms of how it serves the community, so that when Agamemnon sacrifices his daughter Iphigenia he is regarded as a tragic hero since the sacrifice is required for the success of the Greek expedition to Troy (*Fear and Trembling*).

Kierkegaard, however, does recognize duties to a power higher than social norms. Much of *Fear and Trembling* turns on the notion that Abraham's would-be sacrifice of his son Isaac is not for the sake of social norms, but is the result of a "teleological suspension of the ethical". That is, Abraham recognizes a duty to something higher than both his social duty not to kill an innocent person and his personal commitment to his beloved son, viz. his duty to obey God's commands.

But in order to arrive at a position of religious faith, which might entail a "teleological suspension of the ethical", the individual must first embrace the ethical (in the first sense). In order to raise oneself beyond the merely aesthetic life, which is a life of drifting in imagination, possibility and sensation, one needs to make a commitment. That is, the aesthete needs to choose the ethical, which entails a commitment to communication and decision procedures.

The ethical position advocated by Judge Wilhelm in "Equilibrium Between the Aesthetic and the Ethical in the Composition of Personality" (*Either-Or* II) is a peculiar mix of cognitivism and noncognitivism. The metaethics or normative ethics are cognitivist, laying down various necessary conditions for ethically correct action. These conditions include: the necessity of choosing seriously and inwardly; commitment to the belief that predications of good and evil of our actions have a truth-value; the necessity of choosing what one is actually doing, rather than just responding to a situation; actions are to be in accordance with rules; and these rules are universally applicable to moral agents.

The choice of metaethics, however, is noncognitive. There is no adequate proof of the truth of metaethics. The choice of normative ethics is motivated, but in a noncognitive way. The Judge seeks to motivate the choice of his normative ethics through the avoidance of despair. Here despair (*Fortvivlelse*) is to let one's life depend on conditions outside one's control (and later, more radically, despair is the very

possibility of despair in this first sense). For Judge Wilhelm, the choice of normative ethics is a noncognitive choice of cognitivism, and thereby an acceptance of the applicability of the conceptual distinction between good and evil.

From Kierkegaard's religious perspective, however, the conceptual distinction between good and evil is ultimately dependent not on social norms but on God. Therefore it is possible, as Johannes de Silentio argues was the case for Abraham (the father of faith), that God demand a suspension of the ethical (in the sense of the socially prescribed norms). This is still ethical in the second sense, since ultimately God's definition of the distinction between good and evil outranks any human society's definition. The requirement of communicability and clear decision procedures can also be suspended by God's fiat. This renders cases such as Abraham's extremely problematic, since we have no recourse to public reason to decide whether he is legitimately obeying God's command or whether he is a deluded would-be murderer. Since public reason cannot decide the issue for us, we must decide for ourselves as a matter of religious faith.

Kierkegaard's Religion

Kierkegaard styled himself above all as a religious poet. The religion to which he sought to relate his readers is Christianity. The type of Christianity that underlies his writings is a very serious strain of Lutheran pietism informed by the dour values of sin, guilt, suffering, and individual responsibility. Kierkegaard was immersed in these values in the family home through his father, whose own childhood was lived in the shadow of the severe *Indre Mission* (Inner Mission) -- a pietistic cult from Jutland. Kierkegaard's father subsequently became a member of the Moravian Brethren congregation in Copenhagen.

For Kierkegaard Christian faith is not a matter of regurgitating church dogma. It is a matter of individual subjective passion, which cannot be mediated by the clergy or by human artefacts. Faith is the most important task to be achieved by a human being, because only on the basis of faith does an individual have a chance to become a true self. This self is the life-work which God judges for eternity.

The individual is thereby subject to an enormous burden of responsibility, for upon h/er existential choices hangs h/er eternal salvation or damnation. Anxiety or dread (*Angest*) is the presentiment of this terrible responsibility when the individual stands at the threshold of momentous existential choice. Anxiety is a two-sided emotion: on one side is the dread burden of choosing for eternity; on the other side is the exhilaration of freedom in choosing oneself. Choice occurs in the instant (*Øjeblikket*), which is the point at which time and eternity intersect -- for the individual creates through temporal choice a self which will be judged for eternity.

But the choice of faith is not made once and for all. It is essential that faith be constantly renewed by means of repeated avowals of faith. One's very selfhood depends upon this repetition, for according to Anti-Climacus, the self "is a relation which relates itself to itself" (*The Sickness Unto Death*). But unless this self acknowledges a "power which constituted it," it falls into a despair which undoes its selfhood.

Therefore, in order to maintain itself as a relation which relates itself to itself, the self must constantly renew its faith in "the power which posited it." There is no *mediation* between the individual self and God by priest or by logical system (*contra* Catholicism and Hegelianism respectively). There is only the individual's own *repetition* of faith. This repetition of faith is the way the self relates itself to itself and to the power which constituted it, i.e. the repetition of faith *is* the self.

Christian dogma, according to Kierkegaard, embodies paradoxes which are offensive to reason. The central paradox is the assertion that the eternal, infinite, transcendent God simultaneously became incarnated as a temporal, finite, human being (Jesus). There are two possible attitudes we can adopt to this assertion, viz. we can have faith, or we can take offense. What we cannot do, according to Kierkegaard, is believe by virtue of reason. If we choose faith we must suspend our reason in order to believe in something higher than reason. In fact we must believe *by virtue of the absurd*.

Much of Kierkegaard's authorship explores the notion of the absurd: Job gets everything back again by virtue of the absurd (*Repetition*); Abraham gets a reprieve from having to sacrifice Isaac, by virtue of the absurd (*Fear and Trembling*); Kierkegaard hoped to get Regine back again after breaking off their engagement, by virtue of the absurd (*Journals*); Climacus hopes to deceive readers into the truth of Christianity by virtue of an absurd representation of Christianity's ineffability; the Christian God is represented as absolutely transcendent of human categories yet is absurdly presented as a personal God with the human capacities to love, judge, forgive, teach, etc. Kierkegaard's notion of the absurd subsequently became an important category for twentieth century existentialists, though usually devoid of its religious associations.

According to Johannes Climacus, faith is a miracle, a gift from God whereby eternal truth enters time in the instant. This Christian conception of the relation between (eternal) truth and time is distinct from the Socratic notion that (eternal) truth is always already within us -- it just needs to be recovered by means of recollection (*anamnesis*). The condition for realizing (eternal) truth for the Christian is a gift (*Gave*) from God, but its realization is a task (*Opgave*) which must be repeatedly performed by the individual believer. Whereas Socratic recollection is a recuperation of the past, Christian repetition is a "recollection forwards" -- so that the eternal (future) truth is captured in time.

Crucial to the miracle of Christian faith is the realization that over against God we are always in the wrong. That is, we must realize that we are always in sin. This is the condition for faith, and must be given by God. The idea of sin cannot evolve from purely human origins. Rather, it must have been introduced into the world from a transcendent source. Once we understand that we are in sin, we can understand that there is some being over against which we are always in the wrong. On this basis we can have faith that, by virtue of the absurd, we can ultimately be atoned with this being.

Kierkegaard's Politics

Kierkegaard is sometimes regarded as an apolitical thinker, but in fact he intervened stridently in church politics, cultural politics, and in the turbulent social changes of his time. His earliest published essay, for

example, was a polemic against women's liberation. It is a reactionary apologetic for the prevailing patriarchal values, and was motivated largely by Kierkegaard's desire to ingratiate himself with factions within Copenhagen's intellectual circles. This latter desire gradually left him, but his relation to women remained highly questionable.

One of Kierkegaard's main interventions in cultural politics was his sustained attack on Hegelianism. Hegel's philosophy had been introduced into Denmark with religious zeal by J.L. Heiberg, and was taken up enthusiastically within the theology faculty of Copenhagen University and by Copenhagen's literati. Kierkegaard, too, was induced to make a serious study of Hegel's work. While Kierkegaard greatly admired Hegel, he had grave reservations about Hegelianism and its bombastic promises. Hegel would have been the greatest thinker who ever lived, said Kierkegaard, if only he had regarded his system as a thought-experiment. Instead he took himself seriously to have reached the truth, and so rendered himself comical.

Kierkegaard's tactic in undermining Hegelianism was to produce an elaborate parody of Hegel's entire system. The pseudonymous authorship, from *Either-Or* to *Concluding Unscientific Postscript*, presents an inverted Hegelian dialectic which is designed to lead readers away from knowledge rather than towards it. This authorship simultaneously snipes at German romanticism and contemporary Danish literati (with J.L. Heiberg receiving much acerbic comment).

This intriguing pseudonymous authorship received little popular attention, aimed as it was at the literary elite. So it had little immediate effect as discursive action. Kierkegaard sought to remedy this by provoking an attack on himself in the popular satirical review *The Corsair*. Kierkegaard succeeded in having himself mercilessly lampooned in this publication, largely on personal grounds rather than in terms of the substance of his writings. The suffering incurred by these attacks sparked Kierkegaard into another highly productive phase of authorship, but this time his focus was the creation of positive Christian discourses rather than satire or parody.

Eventually Kierkegaard became more and more worried about the direction taken by the Danish People's Church, especially after the death of the Bishop Primate J.P. Mynster. He realized he could no longer indulge himself in the painstakingly erudite and poetically meticulous writing he had practised hitherto. He had to intervene decisively in a popular medium, so he published his own pamphlet under the title *The Instant*. This addressed church politics directly and increasingly shrilly.

There were two main foci of Kierkegaard's concern in church politics. One was the influence of Hegel, largely through the teachings of H.L. Martensen; the other was the popularity of N.F.S. Grundtvig, a theologian, educator and poet who composed most of the pieces in the Danish hymn book. Grundtvig's theology was diametrically opposed to Kierkegaard's in tone. Grundtvig emphasized the light, joyous, celebratory and communal aspects of Christianity, whereas Kierkegaard emphasized seriousness, suffering, sin, guilt, and individual isolation. Kierkegaard's intervention failed miserably with respect to the Danish People's Church, which became predominantly Grundtvigian. His intervention with respect to Hegelianism also failed, with Martensen succeeding Mynster as Bishop Primate. Hegelianism in the

church went on to die of natural causes.

Kierkegaard also provided critical commentary on social change. He was an untiring champion of "the single individual" as opposed to "the crowd". He feared that the opportunity of achieving geniune selfhood was diminished by the social production of stereotypes. He lived in an age when mass society was emerging from a highly stratified feudal order and was contemptuous of the mediocrity the new social order generated. One symptom of the change was that mass society substitutes detached reflection for engaged passionate commitment. Yet the latter is crucial for Christian faith and for authentic selfhood according to Kierkegaard.

Kierkegaard's real value as a social and political thinker was not realized until after his death. His pamphleteering achieved little immediate impact, but his substantial philosophical, literary, psychological and theological writings have had a lasting effect. Much of Heidegger's very influential work, *Being And Time*, is indebted to Kierkegaard's writings (though this goes unacknowledged by Heidegger). Kierkegaard's social realism, his deep psychological and philosophical analyses of contemporary problems, and his concern to address "the present age" were taken up by fellow Scandinavians Henrik Ibsen and August Strindberg. Ibsen and Strindberg, together with Friedrich Nietzsche, became central icons of the modernism movement in Berlin in the 1890s. The Danish literary critic Georg Brandes was instrumental in conjoining these intellectual figures: he had given the first university lectures on Kierkegaard and on Nietzsche; he had promoted Kierkegaard's work to Nietzsche and to Strindberg; and he had put Strindberg in correspondence with Nietzsche. Taking his cue from Brandes, the Swedish literary critic Ola Hansson subsequently promoted this conjunction of writers in Berlin itself. Berlin modernism self-consciously sought to use art as a means of political and social change. It continued Kierkegaard's concern to use discursive action for social transformation.

Chronology of Kierkegaard's Life and Works

1813	born May 5 in Copenhagen (Denmark)
1830	matriculated to the university of Copenhagen
1834	mother died
1837	met Regine Olsen
1838	father died
-	*From the Papers of One Still Living. Published against his Will by S. Kierkegaard (Af en endnu Levendes Papirer -- Udgivet mod hans Villie af S. Kierkegaard)*
1840	passed final theological examination
-	proposed to Regine Olsen, who accepted him
1841	broke off his engagement to Regine Olsen
-	defended his dissertation *On the Concept of Irony with constant reference to Socrates (Om Begrebet Ironi med stadigt Hensyn til Socrates)*

- trip to Berlin, where he attended lectures by Schelling

1842 returned from Berlin

1843 *Either-Or: A Fragment of Life edited by Victor Eremita (Enten-Eller. Et Livs-Fragment, udgivet af Victor Eremita)*

- second trip to Berlin
- *Two Edifying Discourses by S. Kierkegaard (To opbyggelige Taler)*
- *Fear and Trembling: A Dialectical Lyric by Johannes de Silentio (Frygt og Bæven. Dialektisk Lyrik af Johannes de Silentio)*
- *Repetition: A Venture in Experimenting Psychology by Constantin Constantius (Gjentagelsen. Et Forsøg i den experimenterende Psychologi af Constantin Constantius)* (published the same day as *Fear and Trembling*)
- *Three Edifying Discourses by S. Kierkegaard (Tre opbyggelige Taler)*
- *Four Edifying Discourses by S. Kierkegaard (Fire opbyggelige Taler)*

1844 *Two Edifying Discourses by S. Kierkegaard (To opbyggelige Taler)*

- *Three Edifying Discourses by S. Kierkegaard (Tre opbyggelige Taler)*
- *Philosophical Fragments or a Fragment of Philosophy by Johannes Climacus, published by S. Kierkegaard (Philosophiske Smuler eller En Smule Philosophie. Af Johannes Climacus. Udgivet af S. Kierkegaard)*
- *The Concept of Anxiety: A Simple Psychologically-Oriented Reflection on the Dogmatic Problem of Original Sin by Vigilius Haufniensis (Begrebet Angest. En simpel psychologisk-paapegende Overveielse i Retning of det dogmatiske Problem om Arvesynden af Vigilius Haufniensis)*
- *Prefaces: Light Reading for Certain Classes as the Occasion may Require by Nicolaus Notabene (Forord. Morskabslæsning for enkelte Stænder efter Tid og Lejlighed, af Nicolaus Notabene)* (published on the same day as *The Concept of Anxiety*)
- *Four Edifying Discourses by S. Kierkegaard (Fire opbyggelige Taler)*

1845 *Three Addresses on Imagined Occasions by S. Kierkegaard (Tre Taler ved tænkte Leiligheder)*

- *Stages On Life's Way: Studies by Various Persons, compiled, forwarded to the press, and published by Hilarious Bookbinder (Stadier paa Livets Vej. Studier af Forskjellige. Sammenbragte, befordrede til Trykken og udgivne af Hilarius Bogbinder)*
- third trip to Berlin
- *Eighteen Edifying Discourses by S. Kierkegaard* (a collection of the remaindered *Edifying Discourses* from 1843 and 1844)
- in an article in *Fædrelandet* Frater Taciturnus (a character from *Stages on Life's Way*) asked to be lambasted in *The Corsair*

1846 Kierkegaard lampooned in *The Corsair*

- *Concluding Unscientific Postscript to Philosophical Fragments: A Mimetic-Pathetic-Dialectic Compilation, An Existential Plea, by Johannes Climacus, published by S. Kierkegaard (Afsluttende uvidenskabelig Efterskrift til de philosophiske Smuler. -- Mimisk-pathetisk-dialektisk Sammenskrift, Existentielt Indlæg, af Johannes Climacus. Udgiven af S. Kierkegaard)*
- *A Literary Review: "Two Ages" -- novella by the author of "An Everyday Story" -- reviewed by S. Kierkegaard (En literair Anmeldelse af S. Kierkegaard)*

1847 *Edifying Discourses in Different Spirits by S. Kierkegaard (Opbyggelige Taler i forskjellig Aand af S. Kierkegaard)*

- *Works of Love: Some Christian Reflections in the Form of Discourses by S. Kierkegaard (Kjerlighedens Gjerninger. Nogle christelige Overveielser i Talers Form, af S. Kierkegaard)*
- Regine marries Fritz Schlegel

1848 *Christian Discourses by S. Kierkegaard (Christelige Taler, af S. Kierkegaard)*

- *The Crisis and a Crisis in the Life of an Actress by Inter et Inter (Krisen og en Krise i en Skuespillerindes Liv af Inter et Inter)*
- *The Point of View for my Work as an Author: A Direct Communication, A Report to History (Synspunktet for min Forfatter-Virksomhed. En ligefrem Meddelelse, Rapport til Historien, af S. Kierkegaard)* (unpublished)

1849 second edition of *Either-Or*

- *The Lilies of the Field and the Birds of the Air: Three devotional discourses by S. Kierkegaard (Lilien paa Marken og Fuglen under Himlen. Tre gudelige Taler af S. Kierkegaard)*
- *Two Ethico-Religious Treatises by H.H. (Tvende ethisk-religieuse Smaa-Afhandlinger. Af H.H.)*
- *The Sickness Unto Death: A Christian psychological exposition for edification and awakening by Anti-Climacus, edited by S. Kierkegaard (Sygdommen til Døden. En christelig psychologisk Udvikling til Opvækkelse. Af Anticlimacus. Udgivet af S. Kierkegaard)*
- *"The High Priest" -- "The Publican" -- and "The Woman taken in Sin": three addresses at Holy Communion on Fridays by S. Kierkegaard („Ypperstepræsten" -- „Tolderen" -- „Synderinden", tre Taler ved Altergangen om Fredagen. Af S. Kierkegaard)*

1850 *Training in Christianity by Anti-Climacus, Nos. I, II, III, edited by S. Kierkegaard (Indøvelse i Christendom. Af Anti-Climacus -- Udgivet af S. Kierkegaard)*

- *An Edifying Discourse by S. Kierkegaard (En opbyggelig Tale. Af S. Kierkegaard)*

1851 *On My Activity As A Writer by S. Kierkegaard (Om min Forfatter-Virksomhed. Af S. Kierkegaard)*

- *Two Discourses at Holy Communion on Fridays by S. Kierkegaard (To Taler ved Altergangen om Fredagen)*
- *For Self-Examination: Recommended to the Contemporary Age by S. Kierkegaard (Til Selvprøvelse, Samtiden anbefalet. Af S. Kierkegaard)*
- *Judge For Yourselves! Recommended to the present time for Self-Examination. Second series, by S. Kierkegaard (Dømmer Selv! Til Selvprøvelse Samtiden anbefalet. Anden Række, af S. Kierkegaard)* (published posthumously 1876)

1854 Bishop Mynster died

- Martensen appointed bishop
- "Was Bishop Mynster ‘a witness to the truth,’ one of ‘the true witnesses to the truth’ -- *is this the truth?*" by S. Kierkegaard in *Fædrelandet* („Var Biskop Mynster et "Sandhedsvidne", et af "de rette Sandhedsvidner", *er dette Sandhed?"* Af S. Kierkegaard) (the first of 21 articles in *Fædrelandet*)

1855 *This Must Be Said, So Let It Be Said, by S. Kierkegaard (Dette skal siges; saa være det da sagt. Af S. Kierkegaard)*

- *The Instant by S. Kierkegaard (Øjeblikket. Af S. Kierkegaard)*
- *Christ's Judgement on Official Christianity by S. Kierkegaard (Hvad Christus dømmer om officiel Christendom. Af S. Kierkegaard)*
- *God's Unchangeability: A Discourse by S. Kierkegaard (Guds Uforanderlighed. En Tale -- Af S. Kierkegaard)*
- Kierkegaard died November 11.

Friedrich Daniel Ernst Schleiermacher

Friedrich Daniel Ernst Schleiermacher (1768-1834) probably cannot be ranked as one of the greatest German philosophers of the eighteenth and nineteenth centuries (like Kant, Herder, Hegel, Marx, or Nietzsche). But he is certainly one of the most interesting of the second-tier philosophers of the period. Nor was he only a philosopher; he was also an eminent classicist and theologian. Much of his philosophical work was in the philosophy of religion, but from a modern philosophical point of view it is probably his hermeneutics (i.e. theory of interpretation) and his theory of translation that deserve the most attention. This article will attempt to provide a fairly broad overview of his philosophical thought. One thing which will emerge when this is done is that although he has important philosophical debts to many predecessors and contemporaries (including Spinoza, Kant, Friedrich Schlegel, and Schelling), he was above all following in the philosophical footsteps of one predecessor in particular: Herder.

1. Life and Works

Friedrich Daniel Ernst Schleiermacher (1768-1834) was born 1768 in Breslau as son of a reformed clergyman. His earlier education took place in institutions of the Moravian Brethren (Herrnhuter), a strict pietist sect, where he also pursued broader humanistic interests however. Largely as a result of skepticism

about certain Christian doctrines taught there, in 1787 he moved to the more liberal University of Halle. However, he continued in theology (with philosophy and classical philology as minor fields). He passed his theological examinations in Berlin in 1790. This was followed by a period as a private tutor, which ended in 1793, partly it seems due to friction caused by his sympathy with the French Revolution (to which his employer was opposed).

During the periods just mentioned he was heavily occupied with the study and criticism of Kant's philosophy. This work culminated in several unpublished essays -- *On the Highest Good* (1789), *On What Gives Value to Life* (1792-3), and *On Freedom* (1790-3) -- which rejected Kant's conception of the "*summum bonum* [highest good]" as requiring an apportioning of happiness to moral desert, rejected Kant's connected doctrine of the "postulates" of an afterlife of the soul and God, and developed an anti-Kantian theory of the thoroughgoing causal determination of human action but of the compatibility of this with moral responsibility. In 1793-4 he wrote two essays about Spinoza: *Spinozism* and *Brief Presentation of the Spinozistic System*. The main catalyst of these essays was Jacobi's 1785 work *On the Doctrine of Spinoza, in Letters to Mr. Moses Mendelssohn*, which was highly critical of Spinozism, but they also show the influence of Herder's 1787 work *God. Some Conversations*, which championed a modified form of Spinozism. In his two essays Schleiermacher himself embraces a modified form of Spinozist monism similar in character to Herder's (in particular, like Herder, he inclines to substitute for Spinoza's single substance the more active principle of a single fundamental force). He also attempts to defend this position by showing it to be reconcilable with central features of Kant's theoretical philosophy (notably, Kant's doctrine of things in themselves). This neo-Spinozistic position would subsequently be fundamental to Schleiermacher's most important work in the philosophy of religion, *On Religion: Speeches to Its Cultured Despisers* (1799). However, in thus rejecting Jacobi's anti-Spinozism, Schleiermacher seems also to have absorbed something from Jacobi which would be no less important for his future philosophy of religion: the idea (for which his pietist background no doubt made him receptive) that we enjoy a sort of immediate intuition or feeling of God.

During the period 1794-6 Schleiermacher served as a pastor in Landsberg. In 1796 he moved to Berlin, where he became chaplain to a hospital. In Berlin he met Friedrich and August Wilhelm Schlegel and other romantics, became deeply engaged in the romantic movement, and collaborated with the Schlegel brothers on the short-lived but important literary journal *Athenaeum* (1798-1800). Among Schleiermacher's contributions to this journal was a short proto-feminist piece *Idea for a Catechism of Reason for Noble Ladies*. During 1797-9 he shared a house with Friedrich Schlegel. Encouraged by the romantic circle to write a statement of his religious views, in 1799 he published his most important and radical work in the philosophy of religion, *On Religion: Speeches to its Cultured Despisers* (revised editions: 1806, 1821, the latter including significant "explanations," and 1831). This work sought to save religion in the eyes of its cultured despisers (prominent among them some of the romantics) by, inter alia, arguing that human immortality and even God are inessential to religion, diagnosing current religion's more off-putting features in terms of its corruption by worldly bourgeois culture and state-interference, and arguing that there are an endless multiplicity of valid forms of religion. The book won Schleiermacher a national reputation. In the same year (1799) he also published an essay on the situation of the Jews in Prussia, *Letters on the Occasion of the Political-Theological Task and the Open Letter of Jewish Householders*. In this work he rejected a proposed expedient of effecting the Jews' civil

assimilation through baptism (which would, he argues, harm both Judaism and Christianity) and instead advocated full civil rights for them (on certain reasonable conditions). The same year also saw Schleiermacher's composition of the interesting short essay *Toward a Theory of Sociable Conduct*, which is important as his first significant discussion of the art of conversation (an art which would later be central to his dialectics lectures). Finally, 1799 also saw his publication of a highly critical review of Kant's *Anthropology*. This review in particular takes Kant to task for his dualistic philosophy of mind, and his superficial, disparaging attitude towards women and other peoples.

During the following several years Schleiermacher complemented *On Religion* with two substantial publications which were more ethical in orientation: the especially important *Soliloquies* (1800; second edition 1810) and the *Outlines of a Critique of Previous Ethical Theory* (1803). In 1800 he also defended his friend Friedrich Schlegel's controversial and (it is widely agreed) pornographic novel *Lucinde* of the same year in his *Confidential Letters Concerning Friedrich Schlegel's Lucinde* -- a shared proto-feminism constituting a large part of his reason for sympathy with Schlegel's book. During the period 1799-1804 Schleiermacher developed with Schlegel the project of translating Plato's dialogues. As time went on, however, Schlegel left this work to Schleiermacher (which contributed to increasingly difficult relations between the two men after 1800). Schleiermacher's translations appeared during the period 1804-28 (though not all of the dialogues were translated in the end), and are still widely used and admired today.

While in Berlin Schleiermacher developed romantic attachments to two married women, Henriette Herz and Eleonore Grunow -- the latter of which attachments led to scandal and unhappiness, eventually encouraging Schleiermacher to leave the city. He spent the years 1802-4 in Stolpe. By 1804 he was teaching at Halle University. In the period 1804-5 he began lecturing on ethics (as he would do repeatedly until 1832). In 1805 he also began his famous and important lectures on hermeneutics (which he delivered repeatedly until 1833). In 1806 he published the short book *Christmas Eve*, a literary work which explores the meaning of Christian love by depicting a German family's celebration of Christmas Eve (in keeping with *On Religion*'s ideal of (Christian) religion as family- rather than state-centered). In 1806-7 he left Halle as a result of the French occupation, and moved to Berlin. From this time on he began actively promoting German resistance to the French occupation, and the cause of German unity. In 1808 he married Henriette von Willich (a young widow), with whom he had several children. In 1808-9 he became preacher at the Dreifaltigkeitskirche, in 1810 professor of theology at the University of Berlin, and by 1811 he was also a member of the Berlin Academy of Sciences.

After becoming a member of the Academy he often delivered addresses before it, among which several on ethics and one from 1831 on Leibniz's idea of a universal language are especially significant. In 1811 he lectured on dialectics for the first time (as he would do repeatedly until his death, at which time he was in the early stages of preparing a version for publication). In 1813 he published the shortish essay *On the Different Methods of Translation* -- a very important work in translation theory deeply informed by his experience as a translator. In 1818 he lectured on psychology for the first time (as he would do repeatedly until 1833-4). In 1819 he lectured on aesthetics for the first time (as he subsequently did on two further occasions, the last of them in 1832-3). In the same year he also began lecturing on the life of Jesus (as he did again on four further occasions over the following twelve years), thereby inaugurating an important genre of literature on this subject in the nineteenth century. In 1821-2 he published his major work of

systematic theology, *The Christian Faith* (revised edition 1830-1). In 1829 he published two open letters on this work (nominally addressed to his friend Lücke), in which he discusses it and central issues in the philosophy of religion and theology relating to it in a concise and lucid way. He died in 1834.

As can be seen even from this brief sketch of his life and works, a large proportion of Schleiermacher's career was taken up with the philosophy of religion and theology. However, from the secular standpoint of modern philosophy it is his work in such areas as hermeneutics (i.e. the theory of interpretation) and the theory of translation that is more interesting. Accordingly, this article will begin with these more interesting areas of his thought, only turning briefly to his philosophy of religion at the end.

2. Philosophy of Language

Since the topics of language and psychology are central to Schleiermacher's hermeneutics and theory of translation, it may be appropriate to begin with some discussion of his philosophies of language and mind. Schleiermacher nowhere presents his philosophy of language separately; instead, it is found scattered through such works as his lectures on psychology, dialectics, and hermeneutics. The following positions -- all but the last of which are heavily indebted to Herder -- are especially worth noting:

> (1) In his psychology lectures, Schleiermacher takes the following stance on the question of the origin of language (virtually identical to Herder's stance in his *Treatise on the Origin of Language* (1772)): Language's origin is not to be explained in terms of a divine source. Nor is it to be explained in terms of the primitive expression of feelings. Rather, the use of inner language is simply fundamental to human nature. It is the foundation of, and indeed identical with, thought; and it is also the foundation of other distinctively human mental features, in particular self-consciousness and a clear distinguishing of perception from both feeling and desire.
>
> (2) Language (and hence thought) are fundamentally social in nature. More precisely, although inner language is not dependent on a social stimulus (so that even in the absence of that children would develop their own languages), it does already involve a tendency or implicit directedness towards social communication.
>
> (3) Language and thought are not mere additions on top of other mental processes which human beings share with the animals. Rather, they are infused throughout, and lend a distinctive character to, all human mental processes. In particular, they structure human beings' sensory images in distinctive ways.

The next five positions are especially important for Schleiermacher's hermeneutics and theory of translation (to be discussed below):

> (4) Schleiermacher in his early work postulates an identity of thought with linguistic expression. He often equates thought more specifically with *inner* language (he already

does so in his 1812-13 ethics lectures). His main motive behind such a refinement can be seen from the lectures on psychology, which discuss cases in which thought occurs but without arriving at any outward linguistic expression. In later work he seems to retreat somewhat from such identity claims, though in his psychology lectures of 1830 we still find him writing of "the activity of thought in its identity with language."

(5) Schleiermacher adopts a view of meaning which equates it -- not with such items, in principle independent of language, as the referents involved, Platonic forms, or the mentalistic “ideas” favored by the British empiricists and others -- but with word usages, or rules for the use of words. For example, in the hermeneutics lectures he says that “the … meaning of a term is to be derived from the unity of the word-sphere and from the rules governing the presupposition of this unity.”

(6) In his psychology lectures, Schleiermacher argues that thought and conceptualization are not *reducible* to the occurrence of sensuous images (since that would conflict with his position that they require or are identical with language), but he also argues that the latter are an essential *foundation* for the former. This position is also reflected in his strong attraction in some of his later hermeneutics and dialectics lectures to Kant's theory of empirical schemata -- according to which empirical concepts are grounded, or consist, in unconscious rules for the generation of sensuous images -- and to turning it into an account of the nature of all concepts. (This invites the question whether there do not also exist strictly a priori concepts. In his psychology lectures Schleiermacher vacillates in his answer to this question: sometimes implying so, but at other points instead implying -- more consistently with the position just described -- that it is merely that some concepts are *more* distantly abstracted from sensory images than others. The latter is his normal answer in his dialectics lectures as well.)

(7) Human beings exhibit, not only significant linguistic and conceptual-intellectual similarities, but also striking linguistic and conceptual-intellectual diversities, especially between different historical periods and cultures, but even to some extent between individuals within a single period and culture. (Schleiermacher argues, plausibly, that the phenomenon of the linguistic and conceptual-intellectual development of cultures over time is only explicable in terms of linguistic and conceptual-intellectual innovations performed by individuals, which get taken over by the broader culture, becoming part of its common stock.)

(8) Schleiermacher, importantly, develops a much more *holistic* conception of meaning than was yet found in his predecessors (this is the one major respect in which his philosophy of language goes beyond Herder's). At least three aspects of his semantic holism can be distinguished: (a) (As can be seen from a passage quoted above,) he espouses a doctrine of “the unity of the word-sphere.” This doctrine in effect says that the various specific senses which a single word will typically bear and which will normally be distinguished by any good dictionary entry (e.g. the different senses of “impression” in “He

made an impression in the clay," "My impression is that he is reluctant," and "He made a big impression at the party") always form a larger semantic unity to which they each essentially belong (so that any loss, addition, or alteration among them entails an alteration in each of them, albeit possibly a subtle one). (b) He holds that the nature of any particular concept is partly defined by its relations to a "system of concepts." In this connection, the dialectics lectures emphasize a concept's relations as a species-concept to superordinate genus-concepts, relations as a genus-concept to subordinate species-concepts, and relations of contrast to coordinate concepts falling under the same genus-concepts. However, other types of conceptual relationships would be included here as well (e.g. those between "to work," "worker," and "a work"). (c) He holds that the distinctive nature of a language's *grammatical* system (e.g. its system of declensions) is also partly constitutive of the character of the concepts expressed within it. (This last position was also developed at about the same time by Friedrich Schlegel, who has a strong claim to be considered the real founder of modern linguistics, and for whom it constituted one of the main rationales for a new discipline of "comparative grammar" (see his *On the Language and Wisdom of the Indians* (1808)). It was shortly afterwards taken over and used to similar effect by another of the founders of modern linguistics, Wilhelm von Humboldt.)

As was mentioned earlier, with the sole exception of this final feature (semantic holism), this entire Schleiermacherian philosophy of language is heavily indebted to Herder's. However, it arguably also weakens Herder's in certain respects. For example, whereas Herder's version of doctrine (4) normally restricted itself to a claim that thought is essentially dependent on and bounded by thought, Schleiermacher, as we saw, turns it into a doctrine of the outright *identity* of thought with language, or with inner language. But such a strong version of the doctrine seems philosophically problematic -- vulnerable to counterexamples in which thought occurs without any corresponding (inner) language use, and vice versa. Again, as we saw, in later works Schleiermacher tends to add to the Herderian doctrine (5) a thesis that concepts are empirical schemata à la Kant (see (6)). What is problematic about this is arguably not, as it might seem to be, the inclusion of sensory images in meaning per se; Herder had included them as well, doing so is probably reconcilable with a (suitably understood) doctrine of meanings as word usages, and the currently popular Fregean-Wittgensteinian attack on such "psychologism" is probably misguided. What is problematic about it is rather that Kant's theory of empirical schemata had implied a sharp distinction between meanings, conceived as something purely psychological, and word usages, so that Schleiermacher's unmodified reintroduction of the theory implies the same (and hence conflicts with doctrine (5), the doctrine that meaning is word usage). Again, whereas for Herder doctrine (7) was merely an empirically established rule of thumb and admitted of exceptions, Schleiermacher in his ethics and dialectics lectures attempts to give a sort of *a priori proof* of linguistic and conceptual-intellectual diversity even at the individual level as a *universal* fact -- a proof which is not only dubious in itself (both in its (quasi-)a priori status and in its specific details), but also implies the extremely counterintuitive consequence (often explicitly asserted by Schleiermacher) that, strictly speaking, no one can ever understand another person.

3. Philosophy of Mind

Schleiermacher's philosophy of mind is found mainly in his lectures on psychology. It is too extensive to be presented in detail here. But the following four central principles -- all of which have their roots in Herder, and especially in Herder's main work in the philosophy of mind, *On the Cognition and Sensation of the Human Soul* (1778) - are especially striking and important:

> (a) Schleiermacher argues for a strong dependence of the soul (or mind) on the body, and indeed for their identity. However, he resists reductionism in either direction, arguing that both what he calls “spiritualism” (i.e. the reduction of the body to the mind) and “materialism” (i.e. the reduction of the mind to the body) are errors. He refers to the sort of non-reductive unity of mind and body that he instead champions as “life.”
>
> (b) Schleiermacher also identifies the soul (or mind) with ”force.” Thus already in *On Freedom* (1790-3) he writes that the soul is “a force or a composite of forces.”
>
> (c) Schleiermacher argues strongly for the unity of the soul (or mind) within itself; the soul is not composed of separate faculties (e.g. sensation, understanding, imagination, reason, desire). (He himself often works with a twofold distinction between what he refers to as the mind's “organic” (i.e. sensory) and ”intellectual” functions, but he holds these too to be at bottom identical.)
>
> (d) Schleiermacher argues that human minds, while they certainly share similarities, are also deeply different from each other -- not only across social groupings such as peoples and genders, but also at the level of individuals who belong to the same groupings. The deep distinctiveness of individual minds periodically exercises an important influence on the development of society at large -- both in the political-ethical sphere (where Schleiermacher calls the individuals in question “heroes”) and in the sphere of thought and art (where he calls them “geniuses”). The distinctiveness of individual minds cannot be explained by any process of calculation (in particular, it is a mistake to suppose that all minds begin the same and that they only come to differ due to the impact of different causal influences on their development, which might in principle be calculated). It can, however, be understood by means of “divination” (on which more anon).

Finally, one feature of Schleiermacher's philosophy of mind which *distinguishes* it from that of Herder and other predecessors is also worth noting: Schleiermacher says relatively little about *unconscious* mental processes, and when he does mention them often seems skeptical about them. For example, he argues that thought cannot be unconscious, and that so-called “obscure representations” are in fact merely sensuous images which do not involve thoughts.

4. Hermeneutics (i.e. Theory of Interpretation)

Some of Schleiermacher's most important philosophical work concerns the theories of interpretation (“hermeneutics”) and translation. Friedrich Schlegel was an immediate influence on his thought here.

Their ideas on these subjects began to take shape in the late 1790s, when they lived together in the same house for a time. Many of their ideas are shared, and it is often unclear which of the two men was the (more) original source of a given idea. But since Schlegel's surviving treatments are far less detailed and systematic than Schleiermacher's, the latter take on prime importance.

Schleiermacher's theories of interpretation and translation rest squarely on three of the Herder-inspired doctrines in the philosophy of language which were described earlier: (4) thought is essentially dependent on and bounded by, or even identical with, language; (5) meaning is word usage; and (7) there are deep linguistic and conceptual-intellectual differences between people. Doctrine (7) poses a severe challenge to both interpretation and translation, and it is the main task of Schleiermacher's theories to cope with this challenge. Schleiermacher's most original doctrine in the philosophy of language, (8) (semantic holism), is also highly relevant in this connection, for, as Schleiermacher perceives, semantic holism greatly exacerbates the challenge to interpretation and translation posed by (7).

Schleiermacher lectured on hermeneutics frequently between 1805 and 1833. The following are his main principles:

> (a) Hermeneutics is strictly the art of *understanding* verbal communication -- as contrasted, not equated, with explicating, applying, or translating it.
>
> (b) Hermeneutics should be a *universal* discipline -- i.e. one which applies equally to all subjects-areas (e.g. the bible, law, and literature), to oral as well as to written language, to modern texts as well as to ancient, to works in one's own language as well as to works in foreign languages, and so forth.
>
> (c) In particular, the interpretation of sacred texts such as the bible is included within it -- this may not rely on *special* principles, such as divine inspiration (of either the author or the interpreter).
>
> (d) Interpretation is a much more difficult task than is generally realized: contrary to a common misconception that “understanding occurs as a matter of course,” “misunderstanding occurs as a matter of course, and so understanding must be willed and sought at every point.” (This position derives from Schleiermacher's version of principle (7): deep linguistic and conceptual-intellectual diversity.) How, then, is interpretation to be accomplished?
>
> (e) Before the interpretation proper of a text can even begin, the interpreter must acquire a good knowledge of the text's historical context. (The suggestion found in some of the secondary literature that Schleiermacher thinks historical context *irrelevant* to interpretation is absurd.)
>
> (f) Interpretation proper always has two sides: one linguistic, the other psychological.

Linguistic interpretation's task (which rests on principle (5)) consists in inferring from the evidence consisting in particular actual uses of words to the rules that are governing them, i.e. to their usages and thus to their meanings; psychological interpretation instead focuses on an author's psychology. Linguistic interpretation is mainly concerned with what is common or shared in a language; psychological interpretation mainly with what is distinctive to a particular author.

(g) Schleiermacher implies several reasons why an interpreter needs to complement linguistic interpretation with psychological in this way. First, he sees this need as arising from the deep linguistic and conceptual-intellectual distinctiveness of individuals. Such distinctiveness at the individual level leads to the problem for linguistic interpretation that the actual uses of words which are available to serve as evidence from which to infer an author's exact usage or meaning will usually be relatively few in number and poor in contextual variety -- a problem which an appeal to authorial psychology is supposed to help solve by providing additional clues. Second, an appeal to authorial psychology is also required in order to resolve ambiguities at the level of linguistic meaning which occur in particular contexts (i.e. even after the range of meanings available to the author for the word(s) in question is known). Third, in order fully to understand a linguistic act one needs to know not only its linguistic meaning but also what some more recent philosophers have called its “illocutionary” force or intention. For example, if I encounter a stranger by a frozen lake who says to me, “The ice is thin over there,” in order fully to understand this utterance I need to know not only its linguistic meaning (which in this case is clear) but also whether it is being made merely as a factual statement, as a threat, as a joke … (Schleiermacher emphasizes the first of these three considerations most. However, if, as he does, one wants to argue that interpretation needs to invoke psychology *generally*, and if, as I hinted earlier, linguistic and conceptual-intellectual distinctiveness is not the pervasive phenomenon that he normally takes it to be, then it is arguably the latter two considerations that one should consider the more fundamental ones.)

(i) Interpretation also requires two different methods: a “comparative” method (i.e. roughly, a method of plain induction), which Schleiermacher sees as predominating on the linguistic side of interpretation (where it takes the interpreter from the particular uses of a word to the rule for use governing them all), and a “divinatory” method (i.e. roughly, a method of tentative and fallible hypothesis based on but also going well beyond available empirical evidence -- the etymology to keep in mind here is not Latin *divinus* but French *deviner*, to guess or conjecture), which he sees as predominating on the psychological side of interpretation. (The widespread idea in the secondary literature that “divination” is for Schleiermacher a process of psychological self-projection into texts contains a small grain of truth -- in that it is his view that interpretation requires some measure of psychological commonality between interpreter and interpreted -- but is basically mistaken.)

(j) Ideal interpretation is of its nature a holistic activity. (This principle in part rests on but also goes well beyond Schleiermacher's semantic holism.) In particular, any given piece of

text needs to be interpreted in light of the whole text to which it belongs, and both need to be interpreted in light of the broader language in which they are written, their larger historical context, a broader preexisting genre, the author's whole corpus, and the author's overall psychology. Such holism introduces a pervasive circularity into interpretation, for, ultimately, interpreting these broader items in its turn depends on interpreting such pieces of text. Schleiermacher does not see this circle as vicious, however. Why not? His solution is not that all of these tasks can and should be accomplished simultaneously -- something which would be beyond human capacities. Rather, it lies in the (very plausible) thought that understanding is not an all-or-nothing matter but something that comes in *degrees*, so that it is possible to make progress towards full understanding in a piecemeal way. For example, concerning the relation between a piece of text and its whole text, Schleiermacher recommends that we first read through and interpret as best we can each of the parts of the text in turn in order thereby to arrive at an approximate overall interpretation of the text, and that we then apply this approximate overall interpretation in order to refine our initial interpretations of the particular parts (which in turn gives us an improved overall interpretation, which can then be re-applied towards further refinement of the interpretation of the parts, and so on indefinitely).

Schleiermacher's indebtedness to Herder in this theory of interpretation extends far beyond the framework-principles (4), (5), and (7) mentioned earlier. Indeed, Schleiermacher's theory as it has just been described is almost identical to Herder's. Some of this commonality is admittedly due to shared influences (especially Ernesti). But Schleiermacher's theory owes exclusively to Herder the two central moves (often wrongly thought to have been original with Schleiermacher) of supplementing “linguistic” with “psychological” interpretation and of identifying “divination” as the predominant method of the latter. (Herder had introduced these two moves mainly in *On Thomas Abbt's Writings* (1768) and *On the Cognition and Sensation of the Human Soul* (1778).) Schleiermacher's theory as it has just been described in the main merely draws together and systematizes ideas which already lay scattered through a number of Herder's works.

There are two significant exceptions to that rule, however. First, as was mentioned, Schleiermacher exacerbates the challenge to interpretation which principle (7) already poses by introducing principle (8), semantic holism. Second, Schleiermacher's theory explicitly introduces principle (b), the *universality* of hermeneutics. This principle is very much in the spirit of Herder's theory, but it does go beyond its letter. (There were, however, other more explicit precedents -- e.g. van der Hardt, Chladenius, Pfeiffer, Grosch, and Meier.)

Schleiermacher's theory of interpretation also departs from Herder's in certain further respects not yet described. However, it is precisely here that it tends to become most problematic. This point has already been made above in relation to the exact force of the three principles in the philosophy of language which underpin it, (4), (5), and (7). But in addition: Unlike Herder, Schleiermacher, especially in his later work, more closely specifies psychological interpretation as a process of identifying, and tracing the necessary development of, a single authorial “seminal decision [Keimentschluß]” that lies behind a work and unfolds itself as the work in a necessary fashion -- which seems a very unhelpful move to make, for how

many works are composed, and hence properly interpretable, in such a way? Again, whereas Herder includes not only an author's linguistic behavior but also his non-linguistic behavior among the evidence relevant to psychological interpretation, Schleiermacher normally insists on a restriction to the former -- which seems misguided (e.g. the Marquis de Sade's recorded *acts* of cruelty seem no less potentially relevant to establishing the sadistic side of his psychological make-up, and hence to interpreting his texts in light of this, than his cruel statements). Again, unlike Herder, Schleiermacher regards the central role of “divination,” or hypothesis, in interpretation as a ground for sharply distinguishing interpretation from natural science, and hence for classifying interpretation as an art rather than a science -- whereas he should arguably instead have seen it as a ground for thinking interpretation and natural science *similar*. (This mistake was apparently caused by his false assumption that natural science works by something like plain induction -- i.e. roughly: this first *a* is *F*, this second *a* is *F*, this third *a* is *F*, … therefore all *a*s are *F* -- rather than by hypothesis.)

Schleiermacher's theory also tends to play down, obscure, or miss certain arguably important points relating to interpretation that Friedrich Schlegel had already made. Schlegel's treatment of hermeneutical matters, found mainly in his *Philosophy of Philology* (1797) and *Athenaeum Fragments* (1798-1800), largely resembles Schleiermacher's, but it also includes the following three points which are less radical, obscured, or altogether missing in Schleiermacher: (i) Schlegel stresses that (superior or “classical”) texts often express *unconscious* meanings (“Every excellent work … aims at more than it knows” - *Wilhelm Meister* (1798)). Schleiermacher sometimes implies a similar view (most famously in his doctrine that the interpreter should aim to understand an author better than the author understood himself), but Schlegel's version of it is more radical, envisaging indeed an “infinite depth” of meaning largely unknown to the author. (ii) Schlegel emphasizes that a work often expresses some of its important meanings, not explicitly in its parts, but rather through the way in which these are put together to form a whole. This is a very valuable point. Schleiermacher *in a way* makes this point as well, but only as incorporated into and obscured by his more dubious doctrine of the “seminal decision.” (iii) Unlike Schleiermacher, Schlegel, especially in his essay *On Unintelligibility* (1798), stresses that works typically contain confusions, and that it is vitally important for an interpreter to identify and explain these: “It is not enough that one understand the actual sense of a confused work better than the author understood it. One must also oneself be able to know, *characterize*, and even *construe* the confusion even down to its very principles.” This is arguably another very important point.

Be these shortcomings in the details of Schleiermacher's hermeneutics as they may, his pupil Böckh, an eminent classical philologist, subsequently gave a faithful and even more systematic articulation of Schleiermacher's hermeneutics in lectures which were eventually published as Böckh's *Encyclopaedia and Methodology of the Philological Sciences* (1877), and through the combined influence of Schleiermacher's and Böckh's treatments it achieved something like the status of the official hermeneutical theory of nineteenth-century classical scholarship.

5. Theory of Translation

Once again, Schleiermacher develops his theory of translation on the foundation of the Herder-influenced

principles (4), (5), and (7), together with (8), his own holism about meaning, which exacerbates the challenge to translation already posed by (7).

Schleiermacher was himself a masterful translator, whose German translations of Plato are still widely used and admired today, nearly two hundred years after they were done. So his views on translation carry a certain prima facie authority. He explains his theory of translation mainly in the brilliant little essay *On the Different Methods of Translation* (1813). The following are his most important points:

> (a) Translation typically faces the problem of a conceptual gulf between the language of the text to be translated and the translator's home language (as the latter currently exists). (This is an application of principle (7).)
>
> (b) This situation makes translation an extremely difficult task, posing a major obstacle to the attainment of translation's primary goal, the faithful reproduction of meaning. In this connection, Schleiermacher in particular notes the following problem, which one might dub the paradox of paraphrase: If, faced with the task of translating an alien concept, a translator attempts to reproduce its intension by reproducing its extension by means of an elaborate paraphrase in his own language, he will generally find that as he gets closer to the original extension he undermines the original intension in other ways. For example, faced with Homer's word *chlôros*, which Homer sometimes applies to things that we would classify as green (e.g. healthy foliage) but at other times to things that we would classify as yellow (e.g. honey), a translator might attempt to reproduce the extension correctly by translating the word as “green or yellow.” But in doing so he would be sacrificing the original intension in other ways -- for Homer did not *have* the concept green (only *chlôros*), and in addition for Homer *chlôros* was not a *disjunctive* concept. (Schleiermacher also identifies a number of further challenges which often exacerbate the difficulty of translation. For example, he notes that in the case of poetry it is necessary to reproduce not only the semantical but also the musical aspects of the original, such as meter and rhyme -- and this not only as a desideratum over and above the main task of reproducing meaning, but also as an essential *part* of that task, because in poetry such musical features serve as essential vehicles for the precise expression of meaning. Also, he argues that in addition to reproducing meaning a translation should attempt to convey to its readership where an author was being conceptually conventional and where conceptually original, e.g. by using older vocabulary in the former cases and relative neologisms in the latter. Also, he notes that in both of these connections the added requirement or desideratum involved will frequently stand in tension with that of finding the closest semantical fit -- e.g. it will turn out that the word which would best reproduce a rhyme or best reflect a concept's vintage is not the one that is closest in meaning to the word in the original.)
>
> (c) Because of this daunting difficulty the translator needs to possess hermeneutical expertise and to be an “artist” if he is to cope with the task of translation at all adequately.
>
> (d) The conceptual gulf which poses the central challenge here might in principle be tackled

in one of two broad ways: either by bringing the author's linguistic-conceptual world closer to that of the reader of the translation or vice versa. The former approach had in fact been championed by Luther in his classic essay *On Translating: An Open Letter* (1530) and practiced by him in his translation of the bible (he called it *Verdeutschung*, “Germanizing”). However, Schleiermacher finds it unacceptable, mainly because it inevitably distorts the author's concepts and thoughts. Schleiermacher therefore champions the alternative approach of bringing the reader towards the linguistic-conceptual world of the author as the only acceptable one. But how can this possibly be accomplished?

(e) According to Schleiermacher, the key to the solution lies in the plasticity of language. Because of this plasticity, even if the usages of words and hence the concepts expressed by the language into which the translation is to be done *as it currently exists* are incommensurable with the author's, it is still possible for a translator to “bend the language of the translation as far possible towards that of the original in order to communicate as far as possible an impression of the system of concepts developed in it.” (Note that this solution presupposes principle (5).) Consider, for example, a translator facing the challenge of translating Homer's word *aretê* into English. The translator will recognize that nothing in existing English exactly expresses this concept. He will therefore judge that the best way to convey it in English is to modify existing English usage in a systematic way for the course of the translation in order thereby to mimic Greek usage and hence meaning. He will begin by taking the word from existing English which comes closest to *aretê* in meaning, say the word *virtue*. However, he will recognize that the rule for use which governs this word in existing English is still very different from that which governs Homer's word *aretê* so that the two words are still quite sharply different in meaning - that, for example, the descriptive component of the rule which governs the word *virtue* in existing English makes it a solecism to ascribe *virtue* to a habitual liar or a pirate, but quite proper under certain circumstances to ascribe it to a physically weak man, whereas exactly the converse rule governs the word *aretê* in Homer. What therefore will the translator do? He will not simply resign himself to living with this discrepancy. Instead, for the duration of his translation he will modify the rule which governs the word *virtue* in order to make this rule conform (or at least more closely conform) to that which governs Homer's word *aretê* -- for example, he will drop the descriptive rule governing the word *virtue* which was just mentioned and switch to its converse instead, consequently for the duration of his translation writing quite happily of certain habitual liars and pirates as having *virtue* (e.g. Odysseus and Achilles, respectively), but scrupulously avoiding describing any physically weak man as having it. He will thereby succeed in expressing -- or at least come close to expressing -- in English the meaning of Homer's word *aretê*.

(f) This approach entails a strong preference for translating any given word in the original in a uniform way throughout the translation rather than switching between two or more different ways of translating it in different contexts.

(g) This approach also makes for translations which are considerably less easy to read than

those which can be achieved by the alternative approach (*Verdeutschung*). However, this is an acceptable price to pay given that the only alternative is a failure to convey the author's meaning at all accurately. Moreover, the offending peculiarities have a positive value in that they constantly remind the reader of the conceptual unfamiliarity of the material that is being translated and of the “bending” approach that is being employed.

(h) In order to work at all effectively, though, this approach requires that large amounts of relevant material be translated, so that the reader of the translation acquires enough examples of a word's unfamiliar use in enough different contexts to enable him to infer the unfamiliar rule for use involved.

(i) Even this optimal approach to translation has severe limitations, however. In particular, it will often be impossible to reproduce the holistic aspects of meaning -- the several related usages of a given word, the systems of related words / concepts, and the distinctive grammar of the language. And since these holistic features are internal to a word's meaning, this will entail a shortfall in the communication of its meaning by the translation. Reading a translation therefore inevitably remains only a poor second best to reading the original.

(j) Translation is still justified, though -- not only by the obvious consideration that it makes works available to people who want to read them but who are not in the fortunate position of knowing the original languages, but also by the less obvious one that through its “bending” approach it effects a conceptual enrichment of their language.

(k) Nor (Schleiermacher adds in answer to a worry which Herder had expressed) need we fear that this enrichment will deprive our language of its authentic character. For in cases where a real conflict with that character arises, the enrichments in question will soon wither from the language.

Once again, not only the framework principles (4), (5), and (7), but most of these ideas about translation come from Herder. In particular, Schleiermacher's central strategy of “bending” the pregiven language in order to cope with conceptual incommensurability, and his point that it is important to convey the musical aspects of an original (poetic) text in order to convey its meaning accurately, both do so. (Relevant Herderian sources in this connection are the *Fragments on Recent German Literature* (1767-8) and the prefaces of the *Volkslieder* (1774).) However, unlike Schleiermacher's theory of interpretation, which as was mentioned often worsens Herder's, this theory of translation tends to refine Herder's in some modest but significant ways. Among the ideas just adumbrated, examples of this occur in (b), where Schleiermacher's paradox of paraphrase and his ideal of making clear in the translation at which points the author is being conceptually conventional and at which points conceptually original are both novel; (g), where Schleiermacher's point that the resulting peculiarities are not only unavoidable but can actually serve a positive function of reminding readers of the conceptual incommensurability involved and the “bending” approach being employed to cope with it is novel; (h), which is a novel point; (i), where Schleiermacher's point about the in-principle limitation on the successfulness of translations posed by semantic holism is a novel one; and (k), which plausibly contradicts Herder.

6. Aesthetics

Schleiermacher was generally quite self-deprecating about his sensitivity to and knowledge of art (e.g. in *On Religion* and the *Soliloquies*, where he is clearly rather in awe of the greater expertise in this area enjoyed by such romantic friends as the Schlegel brothers), and accordingly he tended to shy away from discussing it in detail in his earlier work. However, he did eventually bring himself to confront the subject systematically, namely in his lectures on aesthetics (first given in 1819, and then again in 1825 and 1832-3).

Part of his motivation behind this eventual confrontation with the subject -- and part of why it remains interesting today -- derives from the fact that the phenomenon of art, and in particular the phenomenon of non-linguistic art (e.g. painting, sculpture, and music), provokes a certain theoretical question which is of fundamental importance, not only for the philosophy of art itself, but also for hermeneutics or the theory of interpretation, and for the philosophy of language which underlies the theory of interpretation: Do non-linguistic arts such as painting, sculpture, and music express meanings and thoughts, and if so how? This question is important for the theory of interpretation because it brings in its train such further questions as whether the theory of interpretation should not include among its proper objects further forms of expression in addition to the linguistic ones treated by Schleiermacher's own hermeneutics, what the appropriate methods of interpretation might be in such further cases, and how such cases and their interpretive methods might relate to the linguistic ones. Moreover, this question is equally important for the philosophy of language which underpins Schleiermacher's theory of interpretation, as embodied in principles (4) and (5). For a positive answer to this question might seem to threaten these two principles, or at least to show that they need radical revision if they are to be defensible.

In his last cycle of aesthetics lectures (1832-3) Schleiermacher initially pursues a very simple strategy for dealing with these issues arising in relation to non-linguistic art; however, he eventually realizes that the strategy in question is untenable, and abandons it for a more promising but also more ambiguous position.

His whole train of thought closely follows one that Herder had already pursued in the *Critical Forests* (1769), and so it may be useful to begin with a brief sketch of the latter. By the time of writing the *Critical Forests* Herder was already committed to his own versions of principles (4) and (5). Accordingly, in reaction to the phenomenon of the non-linguistic arts the book initially set out to argue for a theory of their nature which would preserve consistency with those principles, and it did so in a very straightforward way, denying the non-linguistic arts the ability to express thoughts or meanings *autonomously* of language by denying them the ability to express thoughts or meanings *at all*: whereas poetry has a sense, a soul, a force, music is a mere succession of objects in time, and sculpture and painting are merely spatial; whereas poetry not only depends on the senses but also relates to the imagination, music, sculpture, and painting belong solely to the senses (to hearing, feeling, and vision, respectively); whereas poetry uses *voluntary and conventional* signs, music, sculpture, and painting employ only *natural* ones. However, as Herder proceeded with his book he eventually realized that this simplistic solution was untenable: in the third part of the work he came across the awkward case of

ancient coins, which, though normally non-linguistic, clearly do nonetheless often express meanings and thoughts in pictorial ways. This did not lead him to abandon his versions of principles (4) and (5), however. Instead, it brought him to a more refined account of the non-linguistic arts which was still consistent with those principles: the non-linguistic arts do sometimes express meanings and thoughts, but the meanings and thoughts in question are ones which are *parasitic on a prior linguistic expression or expressibility of them possessed by the artist*. In the fourth part of the book (not published until the mid-nineteenth century, and hence unknown to Schleiermacher) Herder extended this solution from coins to painting, and in subsequent works to sculpture and music as well.

Schleiermacher's aesthetics lectures follow a very similar course. He initially sets out to develop a version of the theory that Herder had initially developed in the *Critical Forests*, correlating the several non-linguistic arts with the different senses as Herder's theory had done (his only significant revision consists in modifying Herder's correlation of sculpture with the sense of touch to include vision as well as touch). Like Herder's initial theory, Schleiermacher's is largely motivated by his prior commitment to principles (4) and (5), which, again like Herder's initial theory, it seeks to vindicate in a naive way: non-linguistic arts, such as music and sculpture, do not express meanings or thoughts *autonomously* of language because they do not express them *at all*. (For example, Schleiermacher argues that music merely expresses physiologically based “life-conditions [Lebenszustände],” not representations or thoughts.) However, rather like Herder with his ancient coins, in the course of developing this naive solution Schleiermacher abruptly confronts a case which forces him to the realization that it is untenable. He develops his naive solution smoothly enough for the cases of music and painting. But in the middle of his discussion of sculpture he suddenly recalls Pausanias's account that the very earliest Greek sculptures were merely rough blocks whose function was to serve, precisely, as symbols of religious *ideas* (oops!). He subsequently goes on to note that an analogous point in fact holds for other non-linguistic arts such as painting as well. Accordingly, at this stage in his lectures he changes tack: He now acknowledges that non-linguistic arts *do* (at least sometimes) express meanings and thoughts after all. And he goes on to vacillate between two new, and conflicting, accounts of that fact: (a) The arts in question do so in such a way that the meanings and thoughts involved are at least sometimes not (yet) linguistically articulable. (In particular, Schleiermacher suggests that the early Greek sculpture just mentioned expressed religious ideas which only *later* got expressed linguistically.) This account would entail abandoning or at least severely revising principles (4) and (5). (b) The arts in question do so in virtue of a pre-existing linguistic articulation or articulability of the same meanings and thoughts in the artist. (Schleiermacher actually only says in virtue of “something universal,” “a representation,” but a dependence on language seems clearly implied.) This account is similar to Herder's final account, and would preserve principles (4) and (5). In the end, then, having renounced his initial -- clearly untenable -- position, Schleiermacher is left torn between these two more plausible-looking positions, which, however, contradict each other.

The eighteenth- and nineteenth-century German hermeneutical tradition as a whole was similarly torn between these two positions. As has already been mentioned, (b) was the considered position at which Herder eventually arrived. But (a) had strong champions as well -- in particular, Hamann, Hegel (concerning architecture and sculpture), and the later Dilthey. The choice between these two positions is a genuinely difficult one, philosophically speaking.

Where does this leave Schleiermacher in relation to the several issues bearing on his theory of interpretation and philosophy of language which, I suggested, encouraged him to undertake this investigation of non-linguistic art in the first place? Concerning the primary question, whether the non-linguistic arts express meanings and thoughts and if so how, he has now realized that they do indeed (sometimes) express meanings and thoughts, but he remains torn on exactly how they do so. Concerning his theory of interpretation, that realization is itself important, because it has shown him that interpretation theory must indeed extend its objects beyond linguistic ones to include at least some that are non-linguistic. But he remains torn on the further questions in this area -- in particular whether, as (a) implies, there will be cases in which the interpretation of non-linguistic art will transcend the interpretation of any associated language or, as (b) implies, it will always be dependent on and restricted by the interpretation of associated language. Finally, concerning the philosophy of language which underpins his theory of interpretation, he remains torn about whether the meanings and thoughts expressed by non-linguistic art are always parasitic on language (position (b)), so that principles (4) and (5) can be retained without qualification or modification, or instead sometimes independent of language (position (a)), so that principles (4) and (5) will either have to be abandoned or (as Hamann had already done in his *Metacritique* (1784)) (re)construed in a way that stretches their reference to “language” and “words” to include not-strictly-linguistic-or-verbal symbol-use by the non-linguistic arts.

Another important motive behind Schleiermacher's treatment of art in his late aesthetics lectures concerns its cultural status, and in particular its cultural status relative to religion. It was an abiding concern of Schleiermacher's from very early in his career until the very end of it to subordinate art to religion. The final cycle of aesthetics lectures is merely the last in a long line of attempts to achieve this goal. It seems to me, however, that, partly for reasons already touched on, this last attempt turns out to be oddly and interestingly self-subverting.

I shall briefly review Schleiermacher's series of attempts to subordinate art, and then explain how this last one proves self-subverting. It was already one of the early Schleiermacher's primary goals to turn contemporary culture, and especially the romantic movement, away from the then fashionable idea that art was the highest possible form of insight towards the idea that religion was. This is an important part of the project of *On Religion* (1799). In this work Schleiermacher criticizes the sort of elevation of art above religion that Goethe and Schiller had begun and the romantics had developed, complains of the trivial nature of modern art, and argues that art ought to subserve religion as Plato had thought. (The early Schleiermacher was in a sense strikingly successful in achieving his goal; after 1799 the leading romantics did indeed increasingly turn away from art towards religion, and to some extent the same was also true of German culture more broadly.)

The ethics lectures of 1812-13 continue the same project in a certain way. There Schleiermacher represents art as of its very nature a collective expression of religious feeling (one which differs in accordance with the differences between religions). In other words, he represents art as only true to its own nature when it subserves religion.

The 1830 psychology lectures play an interesting variation on this theme. There Schleiermacher argues that the perception of beauty is a feeling but one which has a sort of deep cognitive content in that it

expresses the relation of intelligence to Being. This makes it sound very much like religious feeling, and indeed in these lectures it is treated as a sort of close second-in-command to religious feeling. It might seem as though, from Schleiermacher's viewpoint, there was a danger here of art acquiring too independent and exalted a status. However, this danger is partly averted by the fact that he is here talking primarily about *natural* beauty, and only secondarily about artistic.

The 1832-3 aesthetics lectures continue this sort of demoting project, but in a different way. Schleiermacher's initial intention there, it seems, was to demote art (in comparison with religion) in two ways: First, as we saw, the lectures initially set out aiming to give an account of non-linguistic arts (music, painting, and sculpture) which represents them as merely expressive of sensuous feelings and non-cognitive in character. Second, the lectures give an account of poetry which represents it as merely national and indeed merely individual in nature (not universal). Thus the lectures argue that art generally, and therefore poetry in particular, is national in nature, not universal like science and (in a sense) religion, and more radically that poetry has the function of expressing individuality, of resisting even the commonality of a national language (thereby making explicit a potential which is also present, though less realized, in normal language use).

However, this two-fold strategy for demoting art turns out to be curiously self-subverting. For one thing, as we saw, the model of non-linguistic art as merely sensuous and non-cognitive in the end proves unsustainable. Moreover, not only does non-linguistic art turn out to have a cognitive content after all, but in addition this becomes clear from a case (the earliest Greek sculpture) in which the content in question is not trivial but deeply religious in character. Also, this self-subversion would be even more extreme if position (a) won out over position (b). For another thing, poetry's function of expressing individuality implies that it represents Schleiermacher's *highest ethical value.* In short, what was intended as a demotion of art turns willy-nilly into a sort of cognitive-religious and ethical exaltation of it.

7. Dialectics

Most of Schleiermacher's earliest philosophical work was in areas of the subject which might reasonably be described as peripheral in comparison with such central areas as metaphysics and epistemology (in particular, ethics, philosophy of religion, and hermeneutics). This fact, together no doubt with the imposing presence of several competitors who had recently made or were making contributions in those central areas (including Kant, Fichte, Schelling, and Hegel), seems to have spurred Schleiermacher to develop his own treatment of them. The result was his “dialectics,” which he began to present in lecture-form in 1811. (The subject-title calls to mind relevant thought not only in Plato and Aristotle, but also in Kant and Hegel.)

Accordingly, Schleiermacher's dialectics in certain ways carries the marks of a discipline which he felt forced to develop, rather than one for which he had a clear, compelling vision (as he did for his philosophy of religion and hermeneutics for instance). For one thing, the nature of the discipline undergoes a striking shift between its two earliest versions (the lectures of 1811 and 1814-15) -- which have the character of fairly conventional treatments of metaphysical and epistemological issues, already

concerned indeed with resolving disagreements to some extent, but in a purely theoretical way -- and its two main later versions (the lectures of 1822 and the book-fragment from 1833), which make the art of actually resolving disagreements through conversation the main core of the discipline (albeit that “conversation” is here understood in a broad sense so as to include not only the paradigm case of oral communication but also written communication and even dialogue internal to a single person's mind). (With some qualification, this shift might be described as one from a more Aristotelian to a more Socratic-Platonic conception of “dialectics.”)

For another thing, in all of its versions Schleiermacher's dialectics has an oddly rag-bag appearance, including as it does not only material that would traditionally be classified as metaphysics and epistemology, but also large components of philosophy of mind, logic (especially the logic of concepts and judgments; Schleiermacher treats the logic of syllogism in a reductive and rather deprecatory way), philosophy of science, and philosophy of religion.

In its final versions (on which I will focus), the discipline has roughly the following character: Its concern is with what Schleiermacher calls “pure thought,” as distinguished from the thought of everday affairs or art -- i.e. with thought which aims at truth, rather than merely at achieving practical ends or inventing fictions. (Schleiermacher denies, though, that the former is sharply divorced from the latter; rather, it is to some degree implicit in them and vice versa.)

According to Schleiermacher, genuine knowledge of its very nature requires, not only (1) correspondence to reality, but also (2) systematic coherence with *all* knowledge and (3) univeral agreement among people. (The main motive behind this elaborate position seems to derive from the thought that there is in principle no way of determining the fulfillment of condition (1) *directly*, so that believers need to rely on guidance by the fulfillment of conditions (2) and (3).)

(In a well-known early interpretation of Schleiermacher's dialectics the German scholar Manfred Frank accentuated condition (3), attributing to Schleiermacher on this basis a consensus-theory of truth. However, in his recent edition of Schleiermacher's dialectics lectures Frank rightly admits that this interpretation overlooked the realism implied by condition (1). This revision of Frank's early reading of Schleiermacher's dialectics also undercuts Frank's equally well-known early reading of Schleiermacher's hermeneutics, which built upon this ascription to Schleiermacher of a consensus-theory of truth an ascription to him also of a (roughly Gadamerian) conception of interpretation as an ongoing construction of facts about meaning through the development of interpretations.)

Not surprisingly given the strength of the three conditions just mentioned, Schleiermacher considers genuine knowledge to be only an “idea” towards which we can make progress, not something that we can ever actually achieve. (His position here resembles his official position in hermeneutics that the genuine understanding of another person is only something to which we can approximate, not something we can ever actually achieve.)

Schleiermacher's dialectics is largely conceived as a methodology for making such progress. This project proceeds relatively smoothly in connection with conditions (1) and (2). For example, in connection with

(1), Schleiermacher develops certain principles concerning how to form concepts correctly rather than incorrectly (i.e. in such a way that -- to borrow a more recent idiom -- they, their superordinate genus-concepts, their subordinate species-concepts, and their contrasting coordinate concepts “carve nature at the joints”). And in connection with (2), while he acknowledges that the task of forming a totality of knowledge is of its nature incompletable, he nonetheless prescribes what he calls ”heuristic” and “architectonic” procedures for, respectively, amassing the pieces of knowledge and forming them together into a coherent whole.

However, the project runs into deeper difficulties in relation to condition (3). There are two main problems here. First, in addition to the obvious and avowed impossibility of actually accessing all people in order to come to agreement with them, Schleiermacher also identifies a further obstacle in the way of reaching, or even making significant progress towards, agreement with them: the deep differences which occur between different languages and modes of thought. The dialectics lectures themselves fail to find any very promising way of coping with this problem. The 1822 version attempts two ways, but neither looks hopeful. Its first approach consists in hypothesizing a domain of “innate concepts” common to everyone (with certain qualifications, e.g. that these concepts require sensations in order to be actualized). This would certainly solve the problem, but only by contradicting Schleiermacher's normal, and surely philosophically superior, position, from which the problem arose in the first place, that there *is no* such conceptual commonality across all different languages (or even, Schleiermacher would normally add, between all individuals who in some sense share a language). The second approach attempted is an argument that we need to develop a complete history of the differences in question and of how they arose. However, this seems beside the point -- a distraction from the problem rather than a solution to it. In the 1833 book-fragment Schleiermacher in places seems close to giving up on this problem, saying at one point that because of it dialectics must restrict itself to a specific “linguistic sphere,” but at other points he evidently still clings to the hope of finding common ground uniting different “linguistic spheres.” What sort of solution does he have in mind? The sort of solution he may have in mind can perhaps best be seen from an 1831 lecture which he gave on Leibniz's idea of a universal language. In this lecture he in effect argues that it was a mistake on Leibniz's part to suppose that there was *already* a conceptual common ground shared by everyone which could be captured in a universal language (this also amounts to a rejection of his own dubious idea in the 1822 lectures of common “innate concepts”), but that the sort of conceptual common ground that Leibniz had thus wrongly envisaged as *already* existing can nonetheless be *achieved* (or at least approached) for the sciences, namely by cultivating an attitude of openness to the borrowing of conceptual resources from other languages as such resources prove themselves useful for the sciences (a process which, according to Schleiermacher, is in fact already heavily underway, and which is realizable either through outright borrowing of the foreign words in question or through translation of them into one's language in the sort of sensitive way that his theory of translation advocates). Schleiermacher points out that this solution requires an (in any case healthy) shedding of prejudices about the superiority of one's own language, mode of thought, and people over others. This looks like Schleiermacher's most promising solution to the problem in question. He did not, however, live long enough to develop it in detail or to build on it towards a more complete method for resolving interlinguistic disagreements.

Second, and more surprisingly, Schleiermacher's dialectics lectures do not even develop any substantive

account of how to resolve disagreements through conversation *within* a “linguistic sphere.” However, here again it is fortunately possible to supplement the dialectics lectures with extraneous material which goes further in such a direction. One important text in this connection is Schleiermacher's early essay *Toward a Theory of Sociable Conduct* (1799), which is precisely concerned with the art of conversation within a linguistic sphere. This early essay emphasizes the importance of finding a (conceptual) “content” that one shares with one's interlocutor(s), and restricting one's conversation to this. Schleiermacher accordingly recommends there that one begin a conversation guided by a sort of minimal estimate of such content arrived at from one's knowledge of such things as the profession, the educational background, and the class of one's interlocutor(s), but that one thence tentatively and experimentally work outwards towards identifying and exploiting further shared content -- a process which he recommends one should undertake, not by the heavy-handed method of introducing doubtfully shared content directly, but rather by the subtler method of introducing it indirectly in the form of a dimension of allusion and satire which one adds to one's treatment of already established shared content (after which, if the response is positive, it can join the previously established shared content as a proper subject matter for direct treatment). Another important text in this connection is Schleiermacher's hermeneutics lectures, which implicitly revise the earlier account just described in two respects: (a) In that account conversation was to be restricted to conceptual content that was already shared between interlocutors. But as we saw previously, by the time Schleiermacher writes the hermeneutics lectures he is skeptical that people *ever* really share conceptual content. Consequently, he would presumably now set the bar for fruitful conversation somewhat lower than strict sharing. (b) Also, it seems reasonable to infer from his conception of hermeneutics that he would now place less emphasis on discovering preexisting commonalities, or near-commonalities, and more on refining those found and establishing further ones -- namely, in both cases, through adept use of the art of hermeneutics.

Finally, Schleiermacher's hermeneutics lectures also supply a further part of his seemingly missing solution to the problem of reaching agreement through conversation, both for inter- and for intra-linguistic contexts. Clearly, any art of reaching agreement through conversation is going to depend on an art of interpreting interlocutors. Accordingly, the dialectics lectures explicitly assert the dependence of dialectics on hermeneutics (as well as vice versa), Schleiermacher's conception of hermeneutics as a universal discipline ensures its applicability to conversations, and Schleiermacher mentions in the hermeneutics lectures that he sometimes applies his own hermeneutical principles in conversational contexts. In short, Schleiermacher's hermeneutics itself constitutes an important component of his art of reaching agreement through conversation.

In sum, whereas Schleiermacher's final conception of dialectics as a discipline leads one to expect it to provide a fairly detailed set of procedures for resolving both inter- and intra-linguistic disagreements in conversation (analogous to the detailed set of procedures for interpretation which one finds in his hermeneutics), this expectation is largely disappointed by the dialectics lectures themselves. However, one can supplement the dialectics lectures from other texts in order to see how Schleiermacher might have envisaged a fuller solution to this task.

One last point which also deserves mention in this connection is the following. Schleiermacher's most prominent motive for developing such an art of conversation is the epistemological one mentioned earlier.

That may or may not be a good motive in the end. However, Schleiermacher also has further and independent motives behind this art which are more obviously attractive. Thus, the 1831 lecture on Leibniz implies two additional motives behind the intercultural side of the art: first, Schleiermacher's cosmopolitan concern for humanity as a whole in all its diversity constitutes a moral reason for promoting fruitful intercultural dialogue; and second, his sense that insight, far from being our monopoly, is dispersed among many cultures constitutes another reason for us to engage in such dialogue. (Schleiermacher would presumably say that analogous considerations help to justify the intracultural side of the art as well.) Again, the essay *Toward a Theory of Sociable Conduct* emphasizes an additional motive behind the intracultural side of the art. In this essay Schleiermacher does not mention his later epistemological motive at all, but instead focuses on more direct benefits which he sees accruing from and depending on fruitful conversation between members of society, in particular an enrichment of the individual's own limited perspective through his incorporation of the different perspectives of other people. (Schleiermacher would presumably say that an analogous consideration helps to justify the intercultural side of the art as well.) In short, even if it were to turn out that Schleiermacher's predominant epistemological motive for developing an art of inter- and intra-cultural conversation were unpersuasive, such an art might still be highly valuable for other reasons that he has in mind such as these.

Finally, a few further positions from Schleiermacher's dialectics may also be worth mentioning briefly. One striking position is a denial that any concepts, thoughts, or cognitions are either purely a priori in nature or purely empirical, either the product of the “intellectual” function alone or the product of the “organic” function alone. All are the product of *both* functions -- though the *proportions* in which they are involved vary from case to case.

More specifically, as Schleiermacher conceives matters, all are located on a continuum which stretches between the maximally “intellectual” ideas of Being or God and the maximally “organic” chaos of sensations. These two extremes do not themselves involve mixture, Being or God being purely intellectual, while the chaos of sensations is purely organic. However, they do not for that reason constitute counterexamples to the position just mentioned, because they are not themselves strictly speaking concepts, thoughts, or cognitions.

As was previously mentioned, Schleiermacher's theory of concepts also says that they are in each case defined by relations of subsumption under higher concepts, contrast with correlative concepts similarly subsumed, and subsumption of further concepts under them. Subsumption under the non-concept Being and the subsumption of a class of primitive judgments about sensations constitute special cases at the two extremes of this conceptual hierarchy.

Another position which Schleiermacher holds is that the distinction between analytic and synthetic judgments is a merely “relative” one. One reason for this position is probably his view that all judgments are partly empirical in nature (a consideration which anticipates Quine). But what he mainly seems to have in mind is that it is always in some sense up to us to decide how many and which characteristic marks to build into any given subject concept, and therefore how many and which judgments in which that subject concept features will count as analytic or as synthetic.

A last feature of Schleiermacher's dialectics is more puzzling. Schleiermacher notes at one point that he wants to chart a sort of middle course between ancient dialectics, which had the virtue of openness but the vice of courting skepticism, and the dogmatism of the scholastics, for whom everything of importance was pre-decided in an assumed religious principle. His concession to the former position has in effect been described above. But what about his concession to the latter? This takes the form of positing a “transcendental ground” or God which is (1) beyond all oppositions, including those of thought/reality, thought/volition, and concept/judgment, (2) beyond Being (even though Being is itself beyond such oppositions), (3) an essential impulse behind, and accompaniment of, all attempts to know, and (4) not thinkable or linguistically expressible but instead felt. This is all rather mysterious. For example, the philosophical rationale for positing this “transcendental ground” or God as beyond rather than identical with Being is obscure, and so too is the exact way in which it is supposed to be the impulse behind and accompaniment of all attempts to know.

8. Ethics

Schleiermacher's ethical thought divides into two overlapping chronological phases: The first phase -- which stretched from the late 1780's until about 1803 -- was mainly critical in character. Early in this phase, the three unpublished essays *On the Highest Good* (1789), *On What Gives Value to Life* (1792-3), and *On Freedom* (1790-3) mounted a thorough attack on Kant's ethical theory, and at the end of this phase the longer published work *Outlines of a Critique of Previous Ethical Theory* (1803) developed that attack into a more comprehensive and systematic critique of predecessors' ethical theories. The second phase -- which began around 1800 -- was mainly constructive in character. To this phase belong the *Soliloquies* (1800), the *Draft of an Ethics* (1805-6), and Schleiermacher's mature ethics lectures (including the complete draft from 1812-13, as well as a number of later partial drafts).

The three early essays *On the Highest Good*, *On What Gives Value to Life*, and *On Freedom* criticize and reject central tenets of Kant's moral philosophy: in particular, Kant's inclusion in the “*summum bonum* [highest good]” of an apportioning of happiness to moral desert, his position that this must be believed in as a presupposition of morality, so that its own implicit presuppositions, an afterlife of the soul and a God, must be so too (the doctrine of the “postulates”), and his incompatibilism concerning causal determinism and the freedom required for moral responsibility and consequent recourse to the causally indeterministic noumenal realm as the locus for freedom (Schleiermacher's *On Freedom* argues for the causal determination of all human actions, but for the compatibility of this with the freedom required for moral responsibility).

A further area of disagreement with Kant forms the hinge on which Schleiermacher's development of his own constructive ethical theory turns. Kant's fundamental moral principle, the “categorical imperative,” consisted in a requirement of the consistency of an agent's moral maxim (or intention) when universalized, and was conceived by Kant to apply uniformly to *all* human beings. Schleiermacher rejects this position in two ways. First, already in *On What Gives Value to Life*, and then especially in the *Soliloquies*, he argues against the (latter) idea of uniformity in ethics -- instead asserting, in the spirit of Herder (and others influenced by Herder, such as Goethe, Schiller, and the romantics), the value of

diversity or individuality even in the moral sphere. In this connection, Schleiermacher champions not only a (moral) distinctiveness of different human societies vis-à-vis the human species as a whole (this had been Herder's pet cause), but also a (moral) distinctiveness of the individual vis-à-vis his society. (In *On Religion* he makes an analogous case for both societal and individual diversity in religion. His positive valuing of societal and individual diversity naturally also extends beyond morals and religion.)

Second, Schleiermacher also rejects the content of Kant's "categorical imperative," in *On Religion* and the *Soliloquies* championing against this an -- again Herderian -- commitment to *humanity* (in the sense of an ideal of the welfare of all human beings). (In *On Religion* Schleiermacher discusses the historical dimension of this principle of humanity in a Herderian vein, like Herder in his *Ideas for the Philosophy of History of Humanity* (1784-91) stressing the important role of (Christian) religion in advancing it, and interpreting history as its progressive realization.)

This double position of Schleiermacher's might seem to court the following sort of problem: What if the moral values of a society or an individual conflict with the ideal of humanity? (What, for example, if the society is Nazi Germany or the individual Hitler?) In the *Soliloquies* Schleiermacher forestalls this sort of problem by limiting the forms of moral distinctiveness and individuality that he supports to those which are compatible with or even promotive of the ideal of humanity. Thus he expresses his commitment to moral distinctiveness or individuality in such formulas as that a person should be an individual "without violating the laws of humanity," that "each human being should represent humanity in his own way," and that what is valuable is a person's "distinctive being and its relation to humanity."

Similarly, Schleiermacher's championing of (moral) diversity or individuality is always combined with requirements of a measure of conformity with a broader species-wide or societal whole.

This constructive tension between "distinctive [eigentümlich]" and "universal" sides of ethics survives to constitute the central principle of Schleiermacher's mature ethics lectures. There he begins by arguing that very general forms or analogues of such a constructive tension are universal facts of nature -- that all finite beings exhibit such a tension, more specifically that all life does so in the more specific form of a tension between autonomy and social commonality, and more specifically still that all human mental life does so in this same form. He then goes on to derive a moral duty to realize such a tension in one's own person.

This provokes certain questions, to which the answers are not entirely clear. First, is Schleiermacher not here guilty of the so-called "naturalistic fallacy," of attempting to deduce an "ought" from an "is"? The answer to this question would depend on the exact nature of his derivation of the moral duty from the universal facts of nature, which is obscure. Second, how can a synthesis of commonality with individuality both be an unavoidable fact about human nature (e.g. because we can never quite share *any* concepts, we also can never quite share any moral concepts in particular) and be a moral duty? There are two possible answers to this puzzle. One would appeal to Schleiermacher's determinism and compatibilism; that a mode of existence or behavior is inevitable does not for him exclude its moral obligatoriness. The other would instead appeal to the fact that the sort of synthesis in question can come in varying degrees; it might be that *some* degree of moral individuality is indeed inevitable for the reason

mentioned but that the degree which is morally required is greater.

In addition to the central principle just discussed, three further aspects of the ethics lectures are worth mentioning briefly: (a) (As was reflected in the structure of the argument just sketched) Schleiermacher's mature conception of ethics is that it is fundamentally ontological rather than merely prescriptive in character: it concerns the immanence of “reason” in “nature,” and is hence more fundamentally a matter of an ”is” than of a “should.” (b) Accordingly (with an eye to the role of “reason” just mentioned), for Schleiermacher ethics is not fundamentally a matter of sentiments (these, he says, simply vary), but instead of cognitions, or more exactly, of something that grounds both ethical sentiments and ethical cognitions. (Here Schleiermacher is for once close to agreement with Kant.) (c) Accordingly again (but this time with an eye to the predominance of ontology over prescription just mentioned), Schleiermacher divides his ethics into a Doctrine of Goods, a Doctrine of Virtue, and a Doctrine of Duties, treating them in this sequence in order to reflect what he takes to be the greater fundamentalness of goods over virtues and of virtues over duties.

Generally speaking, though, Schleiermacher's ethics lectures are not a great success. They form an unholy mixture of, not only ethics in the usual sense, but also political philosophy, metaphysics, epistemology, and philosophy of mind; lurch back and forth between claims of startling dubiousness and claims of startling banality (with too little in between); and stick all this together with a thick stain of obscurantism and a thin varnish of systematicity. One is left with the impression that, having put the critical phase of his work in ethics behind him, Schleiermacher found that he did not really have enough constructive to say about ethics to fill up the hours in the lecture hall.

9. Political and Social Philosophy

Schleiermacher's political and social philosophy is scattered through a considerable number of works from different periods. Its most systematic, but not necessarily most interesting, statement is found in his lectures on the theory of the state, delivered between 1808-9 and 1833.

Concerning international politics, Schleiermacher's fundamental position is a thoroughly Herderian one: a cosmopolitan commitment to equal moral respect for all peoples in their diversity. This position is already articulated in *On What Gives Value to Life* (1792-3); it is central to *On Religion* (1799) and the *Soliloquies* (1800), in the form of a commitment to the Herderian ideal of “humanity”; and it survives in later works (e.g. in the 1831 lecture on Leibniz's idea of a universal language).

Concerning domestic politics: Schleiermacher was always somewhat reticent about fundamental constitutional questions. To judge from his early enthusiasm for the French Revolution, and his republican-democratic model of an ideal church in *On Religion*, the early Schleiermacher was strongly attracted to republicanism and democracy (like Herder). However, his later position -- while it does still make consent a conditio sine qua non of any genuine state -- is more sympathetic to aristocratic and monarchical forms of government. Thus in his lectures on the theory of the state from 1829-33 he argues that whereas smaller and “lower” states are naturally democratic, large and “higher” ones are naturally aristocratic or

monarchical.

However, Schleiermacher's domestic politics is more consistently radical in another respect: liberalism. (Here again he is indebted to Herder.) Already in 1799 the essay *Toward a Theory of Sociable Conduct* argues that there should be a sphere of free (by which Schleiermacher means especially: state-free) social interaction, in order to make possible the development and communication of individuality, and *On Religion* argues strongly against state-interference in religion, making the liberation of religion from such interference a fundamental part of a program for developing individualism in religion, and diagnosing some of the worst vices of current churches and religion in terms of such interference. This liberalism remains prominent in the ethics lectures of 1812-13, which add to the positions just mentioned a proscription of state interference in the universities. And it is still central to Schleiermacher's political thought in his (otherwise more conservative) late lectures on the theory of the state from 1829-33, in which he argues that the three spheres of sociality, religion, and science (e.g. the universities) lie beyond the legitimate power of the state, and critically notes that the current (Prussian) state falls short of this ideal. Schleiermacher's reasons for his broad liberalism are severalfold, but a fundamental one is the need to free up a domain in which the basic good of *individuality* can develop.

Schleiermacher devotes especially close attention to the question of religion's proper relation to the state (and to other socio-political institutions). As was mentioned, in *On Religion* he has two main reasons for wanting to see religion freed from state interference: first, because he values individualism in religion, the free development of a multiplicity of forms of religion; and second, because he sees state-interference as corrupting the nature of religion by, for example, attracting the wrong sorts of people into leadership positions within the church (men with worldly skills and motives rather than religious ones) and foisting alien political functions onto religious mysteries such as baptism and marriage. He argues that the true socio-political center of religion should instead be the family (a position which he later goes on to illustrate in *Christmas Eve* (1806), a work which depicts in a literary way a sort of ideal interweaving of (Christian) religion with family life).

One especially interesting case to which he applied his general insistence on the freedom of religion from state-interference was that of Prussia's Jews. (Once again, Herder had set the tone here -- both by developing a very sympathetic interpretation of ancient Judaism and by forcefully criticizing modern anti-semitism.) In an early work on the subject of Jewish emancipation in Prussia, *Letters on the Occasion of the Political-Theological Task and the Open Letter of Jewish Householders* (1799), Schleiermacher argues that Jews should receive full citizenship and civil rights, provided only that they compromise in their religious observances to a point enabling them to meet their duties to the state, and that they give up such politically threatening commitments as those to a coming messiah and to their status as a separate nation. He argues that Jews should not have to resort to the expedient of baptism as a means for achieving citizenship and civil rights (as some (Jewish) contemporaries had proposed), on the grounds that this expedient would be detrimental both to the Jews and their religion and to Christianity. In the latter connection his main expressed concern is that it would further water down an already rather watery church. But another concern is clearly that it would in effect amount to yet more interference by the state in a religious mystery (baptism). It is significant to note that Schleiermacher takes this strikingly liberal position concerning the Jews despite himself being rather critical of Judaism as a religion: in *On Religion*

he argues that Reimarus's conception that there are deep continuities between Judaism and Christianity is mistaken, and that although Judaism was a beautiful religion in its day it has long since become corrupted and is now effectively moribund (unlike vibrant Christianity).

A further important aspect of Schleiermacher's socio-political philosophy, especially in its earlier phases, is his proto-feminism (in which he is strongly influenced by Friedrich Schlegel, but also by Herder, who was arguably the real pioneer in this area). This proto-feminism has several sides. First, Schleiermacher encourages women to strive for goods which have traditionally been the monopoly of men. For example, in his short *Idea for a Catechism of Reason for Noble Ladies* (published in the *Athenaeum*) he enjoins women, “Let yourself covet men's culture, art, wisdom, and honor.” Second, as a special case of this, he encourages women to seek sexual fulfillment, and to free themselves from inhibitions about discussing sex. This is one of the central themes of his *Confidential Letters Concerning Friedrich Schlegel's Lucinde* (1800). Third, he sees women as a source of valuable moral and intellectual resources for the benefit and improvement of society as a whole. One example of this is their natural aversion to the sorts of insensitivity and violence to which men are commonly prone, and their potential ability to restrain instead of permitting or even encouraging these. In this vein the *Idea for a Catechism* enjoins women, “You should not bear false witness for men. You should not beautify their barbarism with words and works.” Another (more historically specific) example, discussed in *Toward a Theory of Sociable Conduct*, is the ability of women, due to their broad educations but their freedom from the narrow confines of the professions, to direct social conversation away from limited professional concerns towards deeper and more broadly shared ones (Schleiermacher is thinking especially of the hostesses of salons of the period). Another example can be seen in an argument which Schleiermacher develops especially in his ethics lectures to the effect that women are by nature more attuned to recognizing and respecting individuality, whereas men are more attuned to recognizing and respecting abstract generalizations, and that accordingly one of the key functions of marriage is to bring about a valuable blending of these (equally important) intellectual-moral qualities in each partner. (It should be noted, however, that Schleiermacher later on tended to be more conservative in his views about women.)

It is perhaps worth underscoring that in its broad cosmopolitan concern for other peoples, for Jews, and for women Schleiermacher's socio-political philosophy was continuing a paradigm which was above all the achievement of a single predecessor: Herder.

One final feature of Schleiermacher's socio-political philosophy, especially prominent in the works from 1799-1800, is a broad critique of some central modern socio-economic institutions and a set of proposals for remedying their negative effects. (The *Soliloquies* casts this critique in the form of an attack on the self-satisfaction of the Enlightenment which is very reminiscent of Herder's attack in *This Too a Philosophy of History*.) Three parts of Schleiermacher's case are particularly noteworthy: First, in *Toward a Theory of Sociable Conduct* he implicitly criticizes modern division of labor for the way it blinkers people, inhibiting their development of their own individuality and their sense for the individuality of others. His solution here is the development of a sphere of “sociability,” i.e. a sphere of free conversation and social intercourse, in which such one-sidedness can be overcome. Second, in *On Religion* he criticizes the deadening repetitive labor typical of modern economies as an obstacle to spiritual, and in particular religious, self-development. His solution here is mainly a hope that advances in technology will free

people from the sort of labor in question. Third, in *On Religion* and the *Soliloquies* he criticizes the hedonism, utilitarianism, and materialism of the modern age for preventing people's spiritual and religious self-development. His main solution here is the sort of revival of a vibrant religious and moral life for which *On Religion* and the *Soliloquies* argue.

10. Philosophy of Religion

Schleiermacher's most important and radical work in the philosophy of religion is his *On Religion: Speeches to Its Cultured Despisers* of 1799. (Later editions of this work and his later theological treatise *The Christian Faith* strive for greater Christian orthodoxy, and are consequently as a rule less interesting from a philosophical point of view.)

As its title implies, the project of *On Religion* is to save religion from the contempt of enlightenment and especially romantic skeptics about religion, “its cultured despisers.” At least where the romantics were concerned, the work was strikingly successful in this regard, in the sense that several of them, including Friedrich Schlegel, did in fact turn to religion in the years following the book's publication (though admittedly not to quite the sort of religion that Schleiermacher had envisaged). Schleiermacher's later philosophy of religion is similarly motivated. In his 1829 open letters to Lücke he especially stresses the pressing need to defend religion against the twin threats posed to it by modern natural science and modern historical-philological scholarship.

This project of defending religion against educated skeptics is reminiscent of Kant's similarly motivated critical philosophy. Schleiermacher is also sympathetic to Kant's general strategy of “deny[ing] knowledge in order to make room for faith” in connection with religious matters (*Critique of Pure Reason*, Bxxx), and in particular to Kant's attack on traditional proofs of the existence of God; Schleiermacher himself denies that religion is a form of knowledge or can be based on metaphysics or science. However, as can already be seen from his early unpublished essays *On the Highest Good* (1789) and *On What Gives Value to Life* (1792-3), Schleiermacher's strategy is in other respects defined more by opposition to than by agreement with Kant's. In particular, Schleiermacher sharply rejects Kant's alternative *moral* proof of an otherworldly God and human immortality (Kant's proof of them by showing them to be necessary presuppositions of morality); for Schleiermacher religion can no more be based on morality than on metaphysics or science.

As this stance already suggests, Schleiermacher has a large measure of sympathy with the skeptics about religion whom he means to answer. But the early Schleiermacher's sympathy with them also goes far deeper than this. In *On Religion* he is skeptical about the ideas of God and human immortality altogether, arguing that the former is merely optional (to be included in one's religion or not depending on the nature of one's imagination), and that the latter is positively unacceptable. Moreover, he diagnoses the modern prevalence of such religious ideas in terms of the deadening influence exerted by modern bourgeois society and state-interference in religion. He reconciles this rather startling concession to the skeptics with his ultimate goal of defending religion by claiming that such ideas are inessential to religion. This stance strikingly anticipates such more recent radical religious positions as Mauthner's “godless mysticism.”

(Schleiermacher's later religious thought tended to backtrack on this radicalism, however, restoring God and even human immortality to a central place in religion.)

This naturally leaves one wondering what the content and the epistemological basis of religion *are* for Schleiermacher. As can already be seen from the 1793-4 essays *Spinozism* and *Brief Presentation of the Spinozistic System*, and then again from *On Religion*, the early Schleiermacher follows Spinoza in believing in a monistic principle that encompasses everything, a “one and all.” However, he also modifies Spinoza's conception in certain ways, partly under the influence of Herder (who is mentioned by name in the essays on Spinoza). In particular, whereas Spinoza had conceived his monistic principle as a substance, Schleiermacher follows Herder in thinking of it rather as an original force and the unifying source of a multiplicity of more mundane forces. (Later on Schleiermacher distanced himself from this neo-Spinozistic position. He explicitly denied that he was a follower of Spinoza. And accordingly, in the dialectics lectures he argued that there was an even higher “transcendental ground” *beyond* the Spinozist *natura naturans* or the Herderian highest force. His main motive behind this change of position seems to have been a desire to avoid the heavily charged accusations of Spinozism and pantheism -- which is hardly an impressive motive philosophically speaking.)

So much for the content of religion, as Schleiermacher envisages it. What about its epistemological basis? As was mentioned, for Schleiermacher religion is based neither on theoretical knowledge nor on morality. According to *On Religion*, it is instead based on an intuition or feeling of the universe: “Religion's essence is neither thinking nor acting, but intuition and feeling. It wishes to intuit the universe.”

The term “intuition” here is both revealing and problematic. As Kant had defined it, “*intuition* is that through which [a mode of knowledge] is in immediate relation to [objects]” (*Critique of Pure Reason*, A19). So part of what Schleiermacher means to convey here is some sort of immediate cognitive relation to some sort of object, namely the universe as a single whole. On the other hand, the term “intuition” also imported certain implications which Schleiermacher in fact wanted to avoid. In particular, Kantian pure or empirical intuition required the addition of concepts in order to constitute any sort of insight (“intuitions without concepts are blind” -- *Critique of Pure Reason*, A51), whereas Schleiermacher had in mind a sort of insight unmediated by concepts. In the later editions of *On Religion* he therefore retreated from speaking of “intuition” in connection with religion (instead reserving the term for science), and instead spoke simply of “feeling.” In accordance with this change, *The Christian Faith* then went on to define religion more specifically as a feeling of absolute dependence, or what Schleiermacher also described in his open letters to Lücke as the immediate consciousness of “an immediate existence-relationship.”

This epistemological position looks suspiciously like philosophical sleight-of-hand, however. “Feelings” can be of two very different sorts: on the one hand, non-cognitive “feelings,” such as physical pains and pleasures; on the other hand, “feelings” which incorporate cognitions or beliefs, for example a feeling that such and such is the case. Whereas the possession and awareness of non-cognitive feelings such as pains and pleasures may indeed be conceptually unmediated, beyond mediation by reasons for or against, and in a sense infallible, the possession and awareness of feelings which incorporate cognitions or beliefs, for instance the feeling that such and such is the case, does require conceptual mediation, is subject to reasoning for or against, and is fallible. As can be seen from the neo-Spinozistic content that

Schleiermacher's religious intuition or feeling was originally supposed to have, from his original characterization of it as an intuition in the Kantian sense of an immediate cognitive relation to an object, from his later characterization of it as representing “an immediate existence-relationship,” and so forth, he does not mean religious feeling to be merely non-cognitive, but to incorporate some sort of cognition or belief. However, he also helps himself to the apparent epistemological advantages which belong only to non-cognitive feelings: non-mediation by concepts, transcendence of reasons for or against, and infallibility. In short, it looks as though his epistemological grounding of religion in “feeling” depends on a systematic confusion of these two crucially different sorts of cases.

One further, and less problematic, aspect of the “feeling” on which Schleiermacher bases religion should also be mentioned: its inclusion of *motivating* force, its self-manifestation in *actions*. The wish to include this aspect was one of Schleiermacher's reasons for supplementing religious “intuition” with “feeling” in the first edition of *On Religion*. And his later work stresses this dimension of religious “feeling” as well.

Turning to some further features of Schleiermacher's philosophy of religion in *On Religion*: He recognizes a potentially endless multiplicity of valid religions, and strongly advocates religious toleration. However, he also arranges the various types of religion in a hierarchy, with animism at the bottom, polytheism in the middle, and monotheistic or otherwise monistic religions at the top. This hierarchy makes reasonably good sense given his fundamental neo-Spinozism.

More problematic, however, is a further elaboration of this hierarchy which he introduces: he identifies Christianity as the highest among the monotheistic or monistic religions, and in particular as higher than Judaism. His rationale for this is that Christianity introduces “the idea that everything finite requires higher mediation in order to be connected with the divine” (i.e. the higher mediation of Christ). But this looks contrived. Even if one granted that “higher mediation” was a good thing, do not other monotheistic religions such as Judaism share this putative advantage as well, namely in the form of their prophets? And if the answer is No because prophets are not themselves divine, then why is the mediator's divinity supposed to be such a great advantage?

Moreover, Schleiermacher remarks on the distinctively *polemical* nature of Christianity, the extraordinary extent to which Christianity's religious and moral standpoint is defined by a hostile opposition to other standpoints, and even to dissenting positions within Christianity itself. This is an extremely insightful observation. (For example, one thinks in this connection of Nietzsche's brilliant explanation of Christian values as a deliberate inversion of Greco-Roman values, and of the revealing fact that the Christian word “demon” had earlier been the Greeks' most generic word for a deity; also of the bloody early internal history of Christianity, the Crusades, the Inquisition's treatment of Jews and witches, and similar horrors -- all of which only stopped (or receded) when Christianity became politically impotent in the modern period.) But then, how can a proponent of religious pluralism and toleration like Schleiermacher consistently see this striking trait of Christianity as anything but a serious vice?

On the (flimsy) basis of this perception of Christianity's superiority, Schleiermacher is moved to attempt to reconcile his neo-Spinozism with traditional Christian doctrines as far as possible. This project begins in a modest way in *On Religion*, where for example he works to salvage the Christian doctrine of miracles

in the modified form of a doctrine which includes *all* events as miracles (insofar as viewed from a religious perspective). A similar project is pursued in a much more elaborate (and tedious) way in *The Christian Faith*.

Bibliography

Primary texts

There are two main editions of Schleiermacher's works:

- *Gesamtausgabe der Werke Schleiermachers in drei Abteilungen* (Berlin, 1838-)
- *Kritische Gesamtausgabe* (Berlin / New York, 1984-)
  The latter edition will eventually supersede the former, but is still far from complete.

In addition to the above, the following editions are especially important for philosophers:

- *F. Schleiermacher: Hermeneutik. Nach den Handschriften neu herausgegeben und eingeleitet von Heinz Kimmerle* (second edition, Heidelberg, 1974)
- *Schleiermacher: Hermeneutik und Kritik. Herausgegeben und eingeleitet von Manfred Frank* (seventh edition, Frankfurt am Main, 1999)
- *Friedrich Schleiermacher: Dialektik. Herausgegeben und eingeleitet von Manfred Frank*, 2 vols. (Frankfurt am Main, 2001)
  Note that the above two editions of Schleiermacher's hermeneutics (like their respective translations below) contain different material and should be used together.

Since the publication of the old *Gesamtausgabe* a number of improved editions of other parts of Schleiermacher's corpus have also been published (but not yet superseded by the new *Kritische Gesamtausgabe*).

One further significant resource:

- *Aus Schleiermachers Leben in Briefen*, 4 vols., ed. L. Jonas and W. Dilthey (Berlin, 1858-)

Translations

- *Hermeneutics: The Handwritten Manuscripts*, ed. J. Duke and J. Forstman (Atlanta, 1986)
- *Hermeneutics and Criticism*, ed. A. Bowie (Cambridge, 1998)
- ”On the Different Methods of Translation,” in *German Romantic Criticism*, ed. A.L. Willson (New York, 1982)
- *Dialectic or The Art of Doing Philosophy*, ed. T.N. Tice (Atlanta, 1996) [This contains Schleiermacher's first lecture notes on dialectics from 1811.]

- *Friedrich Schleiermacher's "Toward a Theory of Sociable Conduct" and Essays on Its Intellectual-Cultural Context*, ed. R.D. Richardson (Lewiston, New York, 1995)
- *On the Highest Good*, ed. H.V. Froese (Lewiston, New York, 1992)
- *On What Gives Value to Life*, ed. E. Lawler and T.N. Tice (Lewiston, New York, 1995)
- *On Freedom*, ed. A.L. Blackwell (Lewiston, New York, 1992)
- *Soliloquies*, ed. H. Friess (Chicago, 1957)
- *On Religion: Speeches to Its Cultured Despisers*, ed. R. Crouter (Cambridge, 1988)
- *Christmas Eve: Dialogue on the Incarnation*, ed. T.N. Tice (San Fransisco, 1990)
- *The Life of Jesus*, ed. J. Verheyden (Philadelphia, 1975)
- *The Christian Faith*, ed. H.R. Mackintosh and J.S. Stewart (Edinburgh, 1999)
- *On the "Glaubenslehre,"* ed. J. Duke and F. Fiorenza (Atlanta, 1981) [This is a translation of Schleiermacher's two 1829 open letters to Lücke.]
- *Schleiermacher on Workings of the Knowing Mind*, ed. R.D. Richardson (Lewiston, New York, 1998) [This includes a translation of Schleiermacher's 1799 review of Kant's *Anthropology*.]

Johann Gottfried von Herder

Johann Gottfried von Herder (1744-1803) is a philosopher of the first importance. This claim depends largely on the intrinsic quality of his ideas (of which this article will try to give an impression). But another aspect of it is his intellectual influence. This has been immense both within philosophy and beyond (much greater than is usually realized). For example, Hegel's philosophy turns out to be an elaborate systematic development of Herderian ideas (especially concerning God, the mind, and history); so too does Schleiermacher's (concerning God, the mind, interpretation, translation, and art); Nietzsche is deeply influenced by Herder (concerning the mind, history, and values); so too is Dilthey (in his theory of the human sciences); even J.S. Mill has important debts to Herder (in political philosophy); and beyond philosophy, Goethe was transformed from being merely a clever but conventional poet into a great artist largely through the early impact on him of Herder's ideas.

Indeed, Herder can claim to have virtually established whole *disciplines* which we now take for granted. For example, it was mainly Herder (not, as is often claimed, Hamann) who established fundamental ideas about an intimate dependence of thought on language which underpin modern philosophy of language. It was Herder who, through the same ideas, his broad empirical approach to languages, his recognition of deep variations in language and thought across historical periods and cultures, and in other ways, inspired W. von Humboldt to found modern linguistics. It was Herder who developed modern hermeneutics, or interpretation-theory, in a form that would subsequently be taken over by Schleiermacher and then more systematically formulated by Schleiermacher's pupil Böckh. It was Herder who, in doing so, also established the methodological foundations of nineteenth-century German classical scholarship (which rested on the Schleiermacher-Böckh methodology), and hence of modern classical scholarship generally. It was arguably Herder who did more than anyone else to establish the general conception and the interpretive methodology of our modern discipline of anthropology. Finally, Herder also made vital contributions to the progress of modern biblical scholarship.

---

1. Life and Works

Johann Gottfried von Herder (1744-1803) was born in Mohrungen in East Prussia. His father was a school teacher and he grew up in humble circumstances. In 1762 he enrolled at the University of Königsberg, where he studied with Kant, who accorded him special privileges because of his unusual intellectual abilities. At this period he also began a lifelong friendship with the irrationalist philosopher Hamann. In 1764 he left Königsberg to take up a school-teaching position in Riga. There he wrote the programmatic essay *How Philosophy Can Become More Universal and Useful for the Benefit of the People* (1765); published his first major work, on the philosophy of language and literature, the *Fragments on Recent German Literature* (1767-8); and also an important work in aesthetics, the *Critical Forests* (1769). In 1769 he resigned his position and travelled -- first to France, and then to Strasbourg, where he met, and had a powerful impact on, the young Goethe. In 1771 Herder won a prize from the Berlin Academy for his best-known work in the philosophy of language, the *Treatise on the Origin of Language* (published 1772). From 1771-6 he served as court preacher to the ruling house in Bückeburg. The most important work from this period is his first major essay on the philosophy of history, *This Too a Philosophy of History for the Formation of Humanity* (1774). In 1776, partly through Goethe's influence, he was appointed General Superintendant of the Lutheran clergy in Weimar, a post he kept for the rest of his life. During this period he published an important essay in the philosophy of mind, *On the Cognition and Sensation of the Human Soul* (1778); a seminal work concerning the Old Testament, *On the Spirit of Hebrew Poetry* (1782-3); his well-known longer work on the philosophy of history, the *Ideas for the Philosophy of History of Humanity* (1784-91); an influential essay in the philosophy of religion, *God. Some Conversations* (1787); a work largely on political philosophy, written in response to the French Revolution, the *Letters for the Advancement of Humanity* (1793-7); a series of *Christian Writings* (1794-8) concerned with the gospels of the New Testament; and two works opposing Kant's critical philosophy, the *Metacritique* (1799) (against the theoretical philosophy of the *Critique of Pure Reason*) and the *Calligone* (1800) (against the aesthetics of the *Critique of Judgment*). In addition to the works mentioned, Herder wrote many others during his career as well.

2. Philosophical Style

In certain ways Herder's philosophical texts are easier to read than others from the period. For example, he avoids technical jargon, his writing is lively and rich in examples rather than dry and abstract, and he has no large, complex system for the reader to keep track of. But his texts also have certain peculiarities which can impede a proper understanding and appreciation of his thought, and it is important to be

alerted to these.

To begin with, Herder's writing often seems emotional and grammatically undisciplined in a way that might perhaps be expected in casual speech but not in philosophical texts. This is intentional. Indeed, Herder sometimes deliberately "roughed up" material in this direction between drafts. When writing in this way he is actually often using grammatical-rhetorical figures which can easily look like mere carelessness to an untutored eye but receive high literary sanction from classical sources and are employed artfully (e.g. anacoluthon). Moreover, he has serious philosophical reasons for writing in this way rather than in the manner of conventional academic prose, including: (1) This promises to make his writing more broadly accessible and interesting to people -- a decidedly non-trivial goal for him, since he believes it to be an essential part of philosophy's vocation to have a broad social impact. (2) One of his central theses in the philosophy of mind holds that thought is not and should not be separate from volition, or affect, that types of thinking which aspire to exclude affect are inherently distorting and inferior. Standard academic writing has this vice, whereas spontaneous speech, and writing which imitates it, do not. (3) Herder is opposed to any grammatical or lexical straightjacketing of language, any slavish obedience to grammar books and dictionaries. In Herder's view, such straightjacketing is inimical, not only to linguistic creativity and inventiveness, but also (much worse), because thought is essentially dependent on and confined in its scope by language, thereby to creativity and inventiveness in thought itself.

Another peculiarity of Herder's philosophy is its *unsystematic* nature. This is again deliberate. For Herder is largely hostile towards systematicity in philosophy (a fact reflected both in explicit remarks and in many of his titles: *Fragments* . . . , *Ideas* . . . , etc.). He is in particular hostile to the ambitious sort of systematicity aspired to in the tradition of Spinoza, Wolff, Kant, Fichte, Schelling, and Hegel: the ideal of a theory whose parts form and exhaust some sort of strict overall pattern of derivation. He has compelling reasons for this hostility: (1) He is very skeptical that such systematic designs can be made to work (as opposed to creating, through illicit means, an *illusion* that they do so). (2) He believes that such system-building leads to a premature closure of inquiry, and in particular to the disregarding or distorting of new empirical evidence. Scrutiny of such systems amply bears out these concerns. Herder's well-grounded hostility to this type of systematicity established an important countertradition in German philosophy (which subsequently included e.g. F. Schlegel, Nietzsche, and Wittgenstein).

On the other hand, unlike Hamann, Herder is in *favor* of "systematicity" in a more modest sense: the ideal of a theory which is self-consistent and maximally supported by argument. He by no means always achieves this ideal (so that interpreting him requires more selectivity and reconstruction than is the case with some philosophers). But his failures to do so are often more apparent than real: First, often when he may seem to be guilty of inconsistency he really is not. For he is often developing philosophical dialogues between two or more opposing viewpoints, in which cases it would clearly be a mistake to accuse him of inconsistency in any usual or pejorative sense; and (less obviously) in many other cases he is in effect still working in this dialogue-mode, only without bothering to distribute the positions among different interlocutors explicitly, and so is again really innocent of inconsistency (examples occur in *How Philosophy* and *This Too*). Moreover, he has serious motives for this method of (implicit) dialogue: (1) Sometimes his motive is simply that when dealing with religiously or politically delicate matters it

permits him to state his views but without quite stating them as his own and therefore without inviting trouble. But there are also philosophically deeper motives: (2) He takes over from the precritical Kant an idea (inspired by ancient skepticism) that the best way for the philosopher to pursue the truth is by setting contrary views on a subject into opposition with one another in order to advance towards, and hopefully attain, the truth through their mutual testing and modification. (3) Also, he develops an original variant of that idea on the socio-historical plane: analogously, the way for humankind as a whole to attain the elusive goal of truth is through an ongoing contest between opposing positions, in the course of which the best ones will eventually win out (this idea anticipates, and inspired, a central thesis of J.S. Mill's *On Liberty*). This yields a further motive for the dialogue-method (even where it does not lead Herder himself to any definite conclusion), in effect warranting the rhetorical question, And what does it matter to the cause of humankind and its discovery of truth whether those various opposing positions are advanced by different people or by *the same* person? Second, Herder's appearance of neglecting to give arguments is often, rather, a principled rejection of arguments *of certain sorts*. For example, he has a general commitment to empiricism and against apriorism in philosophy which leads him to avoid familiar sorts of apriorist arguments in philosophy; and a commitment to non-cognitivism in ethics which leads him to refrain from familiar sorts of cognitivist arguments in ethics.

3. General Program in Philosophy

Hamann's influence on Herder's best thought has been greatly exaggerated. But Kant's was early, fundamental, and enduring. However, the Kant who influenced Herder in this way was the *pre*critical Kant of the early and middle 1760's, not the critical Kant (against whom Herder later engaged in the -- distracting and rather ineffective -- public polemics mentioned above). Some of Kant's key positions in the 1760's, sharply contrasting with those which he would later adopt in the critical period, were: a (Pyrrhonist-influenced) skepticism about metaphysics; a form of empiricism; and a (Hume-influenced) non-cognitivism in ethics. Herder took over these positions in the 1760's and retained them throughout his career. It should by no means be assumed that this Herderian debt to the *early* Kant is a debt to a philosophically *inferior* Kant; a good case could be made for the very opposite.

Herder's 1765 essay *How Philosophy* is a key text for understanding both his debt to Kant and the broad orientation of his philosophy. The essay was written under strong influence from Kant, especially, it seems, Kant's 1766 essay *Dreams of a Spirit Seer*, which Kant sent Herder before its publication.

Herder's essay answers a prize question set by a society in Bern: "How can the truths of philosophy become more universal and useful for the benefit of the people?" This question is conceived in the spirit of the *Popularphilosophie* that was competing with school-philosophy at the time. Kant himself tended to identify with *Popularphilosophie* at this period, and Herder's selection of this question shows him doing so as well, though in his case the identification would last a lifetime. Philosophy should become relevant and useful for the people as a whole -- this is a basic ideal of Herder's philosophy.

Largely in the service of this ideal, Herder's essay argues for two sharp turns in philosophy, turns which would again remain fundamental throughout the rest of his career. The first involves a rejection of

traditional metaphysics, and closely follows an argument of Kant's in *Dreams of a Spirit Seer*. Herder's case is roughly this: (1) Traditional metaphysics, by undertaking to transcend experience (or strictly, and a little more broadly, "healthy understanding," which includes, in addition to empirical knowledge, also ordinary morality, intuitive logic, and mathematics), succumbs to unresolvable contradictions between claims, and hence to the Pyrrhonian skeptical problem of an equal plausibility on both sides requiring a suspension of judgment. Moreover (Herder adds in the *Fragments*), given the truth of a broadly empiricist theory of concepts, much of the terminology of traditional metaphysics turns out to lack the basis in experience that is required in order even to be meaningful, and hence is meaningless (the illusion of meaningfulness arising through the role of *language*, which spins on, creating illusions of meaning, even after the empirical conditions of meaning have been left behind). (2) Traditional metaphysics is not only, for these reasons, useless; it is also *harmful*, because it distracts its participants from the matters which should be their focus: empirical nature and human society. (3) By contrast, empirical knowledge (or strictly, and a bit more broadly, "healthy understanding") is free of these problems. Philosophy should therefore be based on and continuous with this.

Herder's second sharp turn concerns ethics. Here he remains indebted to Kant, but also goes further beyond him. Herder's basic claims are these: (1) Morality is fundamentally more a matter of sentiments than of cognitions (Herder's sentimentalism is not crude, however; in subsequent works he stresses that cognition plays a large role in morality as well). (2) Cognitivist theories of morality -- of the sort espoused in this period by Rationalists like Wolff, but also by many other philosophers before and since (e.g. Plato and the critical Kant) -- are therefore based on a mistake, and so useless as means of moral enlightenment or improvement. (3) But (and here Herder's theory moves beyond Kant's), worse than that, they are actually *harmful* to morality, because they *weaken* the moral sentiments on which it really rests. In *This Too* and *On the Cognition* Herder suggests several reasons why: (a) Abstract theorizing weakens sentiments *generally*, and hence moral sentiments in particular. (b) The cognitivists' theories turn out to be so *strikingly* implausible that they bring morality itself into disrepute, people reacting to them roughly along the lines: If this is the best that even the *experts* can say in explanation and justification of morality, then morality must certainly be a sham, and I may as well ignore it and do as I please. (c) Such theories distract people from recognizing, and working to reinforce, the *real* foundations of morality: not an imaginary theoretical insight of some sort, but a set of causal mechanisms for inculcating the moral sentiments. (4) More positively, Herder accordingly turns instead to determining theoretically and promoting in practice just such a set of causal mechanisms. In *How Philosophy* he mainly stresses forms of education and an emotive type of preaching. But he elsewhere also identifies and promotes a much broader set of mechanisms, including: the influence of morally exemplary individuals; morally relevant laws; and literature (along with other art forms). Literature is a special focus of Herder's theory and practice here. He sees it as exerting moral influence in various ways -- e.g. not only through fairly direct moral instruction, but also through the literary perpetuation (or creation) of morally exemplary individuals (e.g. Jesus in the New Testament), and the exposure of readers to other people's inner lives and a consequent enhancement of their sympathies for them (a motive behind Herder's publication of *Volkslieder*, or popular songs, from peoples around the world). Herder's development of this theory and practice of moral pedagogy was lifelong and tireless.

4. Philosophy of Language and Interpretation

On the Origin is Herder's best known work in the philosophy of language, but it is in certain respects unrepresentative and inferior in comparison with other works such as the *Fragments* and should not monopolize attention. *On the Origin* is primarily concerned with the question whether the origin of language can be explained in purely natural, human terms or (as Süßmilch had recently argued) only in terms of a divine source. Herder argues for the former position and against the latter. His argument is quite persuasive, especially when supplemented on its positive side from the *Fragments*. But this argument is unlikely to constitute a modern philosopher's main reason for interest in Herder's ideas about language (deriving its zest, as it does, from a religious background that is no longer ours).

Of much greater modern relevance is Herder's theory of interpretation, including his account of the relation between thought and language. This theory is scattered through a large number of works. The following are its main features:

Herder's theory rests on, but also in turn supports, an epoch-making insight: (1) Such eminent Enlightenment philosopher-historians as Hume and Voltaire had still believed that, as Hume put it, "mankind are so much the same in all times and places that history informs us of nothing new or strange." What Herder discovered, or at least saw more clearly and fully than anyone before him, was that this was false, that peoples from different historical periods and cultures often vary *tremendously* in their concepts, beliefs, (perceptual and affective) sensations, and so forth. He also noted that similar, albeit usually less dramatic, variations occur even between individuals within a single culture and period. (These two positions are prominent in many works, including e.g. *On the Change of Taste* (1766) and *On the Cognition*.) Let us call this twofold principle the principle of radical difference.

(2) Given such radical difference, and the gulf that consequently often divides an interpreter's own thought from that of the person he wants to interpret, interpretation is often an extremely *difficult* task, requiring extraordinary efforts from the interpreter. (Herder does not draw the more extreme -- and misguided -- conclusion to which some recent philosophers have been tempted that it would be *impossible*.)

(3) In particular, the interpreter often faces, and needs to resist, a temptation falsely to *assimilate* the thought which he is interpreting to someone else's, especially his own. (This theme is prominent in *This Too*, for example.)

How is the interpreter to meet the challenge? Herder advances three theses concerning thought and language which underpin the rest of his theory of interpretation (and the first two of which in addition founded the philosophy of language as we know it today):

(4) Thought is essentially dependent on, and bounded in scope by, language -- i.e. one can only think if one has a language, and one can only think what one can express linguistically. (Herder, to his credit,

normally refrains from a more extreme, but philosophically untenable, version of this thesis, favored by some of his successors, which *identifies* thought with language, or with inner language.) One consequence of this thesis for interpretation is that an interpreted subject's language is a reliable indicator of the scope of his thought.

(5) Meanings or concepts are not to be equated with the sorts of items, in principle autonomous of language, with which much of the philosophical tradition has equated them -- e.g. the referents involved, Platonic forms, or "ideas" of the sort championed by the British empiricists and others. Instead, they consist in *usages of words*. Consequently, interpretation will essentially involve pinning down word-usages. (Positions (4) and (5) are already embraced by Herder in the 1760's, e.g. in the *Fragments*.)

(6) Conceptualization is intimately bound up with (perceptual and affective) sensation. More specifically, Herder develops a quasi-empiricist theory of concepts according to which sensation is the source and basis of all our concepts, though we are able to achieve non-empirical concepts by means of a sort of metaphorical extension from the empirical ones -- so that all of our concepts ultimately depend in one way or another on sensation. This position carries the important consequence for interpretation that any understanding of a concept must somehow capture its basis in sensation. (For this position, see e.g. *On the Cognition*.)

Herder also has two further basic principles in interpretation-theory:

(7) A principle of *secularism* in interpretation: the interpretation of texts must never rely on religious assumptions or means, even when the texts are sacred ones. (This principle is already prominent in works from the 1760's.)

(8) A principle of *methodological empiricism* in interpretation: interpretation must always be based on, and kept strictly faithful to, exact observations of linguistic (and other relevant) evidence. (This principle is again already prominent in the 1760's, e.g. in the *Fragments* and *On Thomas Abbt's Writings* (1768).)

Beyond this, Herder also advances a further set of interpretive principles which can easily sound much more "touchy-feely" at first hearing (the first of them rather literally so!), but which are in fact on the contrary quite "hard-nosed":

(9) Herder proposes (prominently in *This Too*) that the way to bridge radical difference when interpreting is through *Einfühlung*, "feeling one's way in." This proposal has often been thought (e.g. by Meinecke) to mean that the interpreter should perform some sort of psychological self-projection onto texts. But that is emphatically *not* Herder's idea -- for that would amount to exactly the sort of assimilation of the thought in a text to one's own which he is above all concerned to *avoid*. As can be seen from *This Too*, what he has in mind is instead an arduous process of historical-philological inquiry. What, though, more specifically, is the cash value of the metaphor of *Einfühlung*? It has at least five components: (a) Note, first, that the metaphor implies (once again) that there typically exists radical difference, a gulf, between an interpreter's mentality and that of the interpreted subject, making interpretation a difficult, laborious

task (it implies that there is an "in" there which one must carefully and laboriously "feel one's way into"). (b) It also implies (*This Too* shows) that the "feeling one's way in" should include thorough research not only into a text's use of language but also into its historical, geographical, and social context. (c) It also implies a claim - based on Herder's quasi-empiricist theory of concepts -- that in order to interpret a subject's language one must achieve an imaginative reproduction of his (perceptual and affective) sensations. (d) It also implies that hostility in an interpreter towards the people he interprets will generally distort his interpretation, and must therefore be avoided (though Herder is equally opposed to excessive *identification* with them for the same reason). (e) Finally, it also implies that the interpreter should strive to develop his grasp of linguistic usage, contextual facts, and relevant sensations to the point where this achieves something like the same immediacy and automaticness that it had for a text's original audience when *they* understood the text in light of such things (so that it acquires for him, as it had for them, the phenomenology more of a *feeling* than a cognition).

(10) In addition, Herder insists (e.g. in the *Critical Forests*) on a principle of *holism* in interpretation. This principle rests on several motives, including: (a) Pieces of text taken in isolation are typically ambiguous in various ways (in relation to background linguistic possibilities). In order to resolve such ambiguities, one needs the guidance provided by surrounding text. (b) That problem arises *once* a range of possible linguistic meanings, etc. is established for a piece of text. But in the case of a text separated from the interpreter by radical difference, knowledge of such a range itself presents a problem. How, for example, is he to pin down the range of possible meanings, i.e. possible usages, for a word? This requires collation of the word's actual uses and inference from these to the rules that govern them, i.e. to their usages, a collation which in turn requires looking to remoter contexts in which the same word occurs (other parts of the text, other works in the author's corpus, works by other contemporaries, etc.), or in short: holism. (c) Authors typically write a work *as* a whole, conveying ideas not only in its particular parts but also through the way in which these fit together to make up a whole (either in instantiation of a general genre or in a manner more specific to the particular work). Consequently, readings which fail to interpret the work as a whole will miss essential aspects of its meaning -- not only the ideas in question themselves but also meanings of the particular parts on which they shed important light.

(11) In *On Thomas Abbt's Writings*, *On the Cognition*, and elsewhere Herder makes one of his most important innovations: interpretation must supplement its focus on word-usage with attention to authorial *psychology*. Herder implies several reasons for this: (a) As already mentioned, Herder embraces a quasi-empiricist theory of concepts which implies that in order to understand an author's concepts an interpreter must recapture his relevant sensations. (b) As Quentin Skinner has recently stressed, understanding the linguistic meaning of an utterance or text is only a necessary, not a sufficient, condition for understanding it *tout court* -- one needs, in addition, to establish the author's illocutionary *intentions*. For example, a stranger tells me, "The ice is thin over there"; I understand his linguistic meaning perfectly; but is he simply informing me?, warning me?, threatening me?, joking? . . . (c) Skinner implies that one can determine linguistic meanings prior to establishing authorial intentions. That may *sometimes* be so (e.g. in the example just given). But is it *generally*? Herder implies not. And this seems right, because commonly the linguistic meaning of a formula is ambiguous (in terms of background linguistic possibilities), and in order to identify the relevant meaning one must turn, not only (as previously mentioned) to larger bodies of text, but also to hypotheses, largely derived therefrom,

about the author's intentions (e.g. about the subject-matter he intends to treat). This is a further reason why interpreters must invoke psychology. (d) Herder also (as recently mentioned) stresses that an author often conveys ideas in his work, not explicitly in its verbal expressions, but rather via these and the way in which they are put together to form a textual whole (either in instantiation of a general genre or in a manner more specific to the particular text). It is necessary for the interpreter to capture these ideas both for their own sakes and because doing so is often essential for resolving ambiguities at the level of particular verbal expressions. (e) Herder also refers to the second limb of his doctrine of radical difference -- *individual* variations in mode of thought even within a single culture and period -- as a source of the need for psychological interpretation. Why does any special need arise here? Part of the answer seems to be that when one is dealing, for example, with a concept that is distinctive of a particular author rather than common to a whole culture, one typically faces a problem of *relative paucity and lack of contextual variety* in the actual uses of the word available as empirical evidence from which to infer the rule for use, or usage, constitutive of its meaning. Hence one needs extra help -- and the author's general psychology may provide this.

(12) In the same works Herder also indicates that interpretation, especially in its psychological aspect, requires the use of *divination*. This is another principle which can sound disturbingly "touchy-feely" at first hearing -- in particular, it can sound as though Herder means some sort of prophetic process that has a religious basis and is perhaps even infallible. However, what he really has in mind is (far more sensibly) a process of hypothesis, based on meager empirical evidence, but also going well beyond it, and therefore vulnerable to subsequent falsification, and abandonment or revision if falsified.

(13) Finally, a point concerning the general nature of interpretation and its subject-matter: After Herder, the question arose whether interpretation was a science or an art. Herder does not really address this question. But his inclination would clearly be to say that it is *like* rather than unlike natural science (pace a reading in the German secondary literature which makes him out to be a sort of proto-Gadamer). There are several reasons for this: (a) He assumes (as did virtually everyone at this period) that the meaning of an author's text is as much an *objective* matter as the subjects addressed by the natural scientist. (b) The *difficulty* of interpretation that results from radical difference, and the consequent need for a *methodologically subtle* and *laborious* approach to it in many cases, make for another point of similarity between interpretation and natural science. (c) The essential role of "divination" qua *hypothesis* in interpretation constitutes a further point of similarity between it and natural science. Moreover, (d) even the subject-matter of interpretation is not, in Herder's view, sharply different from that dealt with by natural science: the latter investigates physical processes in nature in order to determine the forces that underly them, but similarly interpretation investigates human verbal (and non-verbal) physical behavior in order to determine the forces that underly *it* (Herder explicitly identifying mental conditions, including conceptual understanding, as "forces").

Herder's theory owes many debts to predecessors. Hamann has commonly been credited with introducing the revolutionary doctrines (4) and (5). But that seems a mistake; Herder was already committed to them in the 1760's, Hamann only later. Herder's debts are rather to a group of authors influenced by Wolff including Abbt and Süßmilch (for (4)) and especially Ernesti (for (1), (2), (5), (7), (8), and (10)). However, Herder's borrowings incorporate important refinements, and his overall

contribution is enormous.

Herder’s theory was taken over almost in its entirety by Schleiermacher in his hermeneutics lectures. Schleiermacher’s theory is also directly influenced by sources shared with Herder, especially Ernesti. But such fundamental and famous positions in it as Schleiermacher’s supplementing of "linguistic" with "psychological" interpretation and identification of "divination" as the method especially of the latter are due entirely to Herder. Moreover, where Herder and Schleiermacher *do* occasionally disagree, Herder’s position is almost always philosophically superior.

5. Philosophy of Mind

Herder in *On the Cognition* and elsewhere also develops an extremely interesting and influential position in the philosophy of mind. The following are some of its central features.

Herder’s position is uncompromisingly *naturalistic* and *anti-dualistic* in intent. In *On the Cognition* he tries to erase the division between the mental and the physical in two specific ways: First, he advances a theory that minds consist in *forces* [Kräfte] which manifest themselves in people’s bodily behavior -- just as physical nature contains forces which manifest themselves in the behavior of bodies. (Note that the general notion of mental "forces" can already be found before Herder in Rationalists such as Wolff and Süßmilch.) He is officially agnostic on the question of what force is, except for conceiving it as something apt to produce a type of bodily behavior, and as a real source thereof (not something reducible thereto). This, strictly speaking, frees the theory from some common characterizations and objections (e.g. vitalism). But it also leaves the theory with enough content to have great virtues over rival theories: (1) The theory ties mental states conceptually to corresponding types of bodily behavior -- which seems correct, and therefore marks a point of superiority over dualistic theories, and indeed over mind-brain identity theories as well. (2) On the other hand, it also avoids *reducing* mental states to bodily behavior -- which again seems correct, in view of such obvious facts as that we can be, and indeed often are, in mental states which happen to receive no behavioral manifestation, and hence marks a point of superiority over outright behaviorist theories.

Second, Herder also tries to explain the mind in terms of the phenomenon of *irritation* [Reiz], a phenomenon recently identified by Haller and exemplified by muscle fibers contracting in response to direct physical stimuli and relaxing upon their removal -- in other words, a phenomenon which, while basically physiological, also seems to exhibit a transition to mental characteristics. There is an ambiguity in Herder’s position here: usually, he wants to resist physicalist reductionism, and so would resist saying that irritation is purely physiological and fully constitutes mental states. But in the 1775 draft of *On the Cognition* and even in parts of the published version this *is* his position. And from a modern standpoint, this is a further virtue of his account (though we would certainly today want to recast it in terms of different, and more complex, physiological processes than irritation). This line of thought might seem at odds with his first one (forces). But it need not be. For, given his official agnosticism about what forces are, it could, so to speak, fill in the "black box" of the hypothesized real forces, namely in physicalist terms. In other words, it turns out (not as a conceptual matter, but as a contingent one) that the real forces

in question consist in physiological processes.

Herder’s philosophy of mind also holds that the mind is a *unity*, that there is no real division between its faculties. This position contradicts theorists such as Sulzer and Kant. However, it is not in itself new with Herder (or Hamann), having already been central to Rationalism, especially Wolff. Where Herder (with Hamann) *is* more original is in rejecting the Rationalists’ reduction of sensation and volition to cognition; establishing the unity thesis in an empirical rather than apriorist way; and adding a normative dimension to it -- this is not only how the mind *is* but also how it *ought* to be. This last feature can sound incoherent, since if the mind is this way by its very nature, what sense is there in prescribing to people that it should be so rather than otherwise? But Herder’s idea is in fact the coherent one that, while the mind is indeed this way by its very nature, people sometimes behave as though one faculty could be abstracted from another, and try to effect that, and this then leads to various malfunctions, and should therefore be avoided.

Herder’s whole position on the mind’s unity rests on three more specific doctrines of intimate mutual involvements between mental faculties, and of malfunctions that arise from striving against these, doctrines which are in large part empirically motivated and hence lend the overall position a sort of empirical basis:

A first concerns the relation between thought and language: Not only does language of its very nature express thought (an uncontroversial point), but also (as noted earlier) for Herder thought is dependent on and bounded by language. Herder bases this further claim largely on empirical grounds (e.g. about how children’s thought develops with language acquisition). The normative aspect of his position here is that attempts (in the manner of some metaphysics) to cut language free from the constraints of thought or (a more original point) vice versa lead to nonsense.

A second area of intimate mutual involvement concerns cognition and volition, or affects. The claim that volition is and should be based on cognition is not particularly controversial. But Herder also argues the converse, that all cognition is and should be based on volition, on affects (and not only on such relatively anemic ones as the impulse to know the truth, but also on less anemic ones). He is especially concerned to combat the idea that *theoretical work* is or should be detached from volition, from affects. In his view, it never really is even when it purports to be, and attempts to make it so merely impoverish and weaken it. His grounds for this whole position are again mainly empirical.

A third area of intimate mutual involvement concerns thought and sensation. Conceptualization and belief, on the one hand, and sensation, on the other, are intimately connected according to Herder. Thus he advances the quasi-empiricist theory of concepts mentioned earlier, which entails that all our concepts (and hence also all our beliefs) ultimately depend in one way or another on sensation. And conversely, he argues -- anticipating much recent work in philosophy -- that there is a dependence in the other direction as well, that the character of our sensations depends on our concepts and beliefs. Normatively, he sees attempts to violate this interdependence as inevitably leading to intellectual malfunction -- e.g., as already mentioned, metaphysicians’ attempts to cut entirely free from the empirical origin of our

concepts lead to meaninglessness. His grounds for this whole position are again largely empirical.

In a further seminal move Herder also argues that (linguistic) meaning is fundamentally social -- so that thought and other aspects of human mental life (as essentially articulated in terms of meanings), and therefore also the very self (as essentially dependent on thought and other aspects of human mental life, and defined in its specific identity by theirs), are so too. Herder's version of this position seems meant only as an empirically-based causal claim. It has since fathered attempts to generate more ambitious arguments for stronger versions of the claim that meaning -- and hence also thought and the very self -- is socially constituted (e.g. by Hegel, Wittgenstein, Kripke, and Burge). However, it may well be that these more ambitious arguments do not work, and that Herder's version is exactly what should be accepted.

Herder also, in tension though not contradiction with this, holds that (even within a single culture and period) human minds are as a rule deeply *individual*, deeply different from each other -- so that in addition to a generalizing psychology we also need a psychology oriented to individuality. This is an important idea which has strongly influenced subsequent thinkers (e.g. Schleiermacher, Nietzsche, Proust, Sartre, and Manfred Frank). Herder advances it only as an empirical rule of thumb. By contrast, a prominent strand in Schleiermacher and Frank purports to make it an a priori universal truth. But Herder's position is again arguably the more plausible one.

Finally, like predecessors in the Rationalist tradition and Kant, Herder sharply rejects the Cartesian idea of the mind's self-transparency -- instead insisting that much of what occurs in the mind is unconscious, so that self-knowledge is often deeply problematic. This is another compelling position which has had a strong influence on subsequent thinkers.

This whole Herderian philosophy of mind owes much to predecessors, especially in the Rationalist tradition. But it is also in many ways original. The theory is important in its own right. And it also exercised enormous influence on successors (e.g. on Hegel in connection with anti-dualism, the role of physical behavior in mental conditions, faculty-unity, and the sociality of meaning, thought, and self; on Schleiermacher in connection with anti-dualism and faculty-unity; and on Nietzsche in connection with the interdependence of cognition and volition, or affects, the individuality of the mind and the need for an individualistic psychology, and the mind's lack of self-transparency).

6. Aesthetics

In the *Critical Forests* (1769, though the important fourth part was not published until the middle of the nineteenth century) Herder sets out to argue for the following aesthetic theory: whereas music is a mere succession of objects in time, and sculpture and painting are merely spatial, poetry has a sense, a soul, a force; whereas music, sculpture, and painting belong solely to the senses (to hearing, feeling, and vision, respectively), poetry not only depends on the senses but also relates to the imagination; whereas music, sculpture, and painting employ only *natural* signs, poetry uses *voluntary and conventional* signs. This theory was taken over (with minor modifications) by Schleiermacher in his aesthetics lectures, and it has sometimes been touted as Herder's main achievement in aesthetics. But it is a naive theory, and his real

achievements in aesthetics are other than and contrary to it.

As noted earlier, Herder's philosophy of language is committed to the two doctrines that thought is essentially dependent on and bounded by language, and that meaning is word-usage. This invites certain questions: These doctrines plausibly break with an Enlightenment assumption that thought and meaning are in principle autonomous of whatever material, perceptible expressions they may happen to receive. Following Charles Taylor, we might call such a move one to "expressivism." But what form should expressivism take exactly? Is the dependence of thought and meaning on external symbols strictly one on *language* (in the usual sense of "language")? Or is it not rather a dependence on a broader range of symbolic media including, besides language, also such things as painting, sculpture, and music, so that a person might be able to entertain thoughts which he was not able to express in language but only in some other symbolic medium? Let us call the former position *narrow expressivism* and the latter *broad expressivism*.

Also, is Herder's own position narrow expressivism or broad expressivism? It might seem at first sight that his two doctrines themselves already answer this question in favor of narrow expressivism because of their reference to "language" and "words." However, matters are not quite so simple. For one thing, such terms easily lend themselves to broadened uses which might include media beyond language in the usual sense. For another, precisely such a broadening actually occurs in a philosopher closely connected with Herder: Hamann. In his *Metacritique* (1784), Hamann is just as much verbally committed to the two doctrines in question as Herder. But he embraces broad expressivism. And he does so quite consistently, because he understands the terms "language" and "word" as they occur in the doctrines in unusually broad senses -- for example, he explicitly includes as forms of the "language" on which he says thought depends not only language in the usual sense but also painting, drawing, and music.

Nonetheless, Herder's considered position *is* in fact the narrow expressivism that his two doctrines initially seem to suggest (so that his verbal sharing of these doctrines with Hamann masks an important difference of philosophical position between them).

Moreover, after much wrestling with the subject, Herder eventually developed a particularly compelling version of narrow expressivism. The key work in this connection is the *Critical Forests*. By the time of writing this work, Herder was already committed to the two doctrines mentioned, and, as this would suggest, from the start in the *Critical Forests* he is committed to narrow expressivism. However, his commitment to it is initially unsatisfactory and inconsistent. For one thing, it initially takes the extreme and implausible form of denying to the non-linguistic arts any capacity to express thoughts *autonomously* of language by denying that they can express thoughts *at all*. This is the force of the naive theory described earlier which the work sets out to develop. Adding inconsistency to this unsatisfactoriness, Herder is from the start in the work also committed to saying (more plausibly) that visual art *does* express thoughts -- e.g. he intervenes in a quarrel between Lessing and Winckelmann on the question of whether linguistic art (especially poetry) or visual art (especially sculpture) is expressively superior *in ways which tend to support Winckelmann's case for visual art*. This unsatisfactoriness and inconsistency result from the fact that Herder has not yet realized that it is perfectly possible to reconcile narrow expressivism with the attribution of thoughts to non-linguistic art, namely *by insisting that the thoughts*

expressed by non-linguistic art must be derivative from and bounded by the artist's capacity for linguistic expression. However, by the time Herder writes the later parts of the *Critical Forests*, he has found this solution. Thus in the third part, focusing on a particularly instructive example, he notes that the pictorial representations on Greek coins are typically allegorical. And by the fourth part he is prepared to say something similar about much painting as well, writing, for example, of "the sense, the allegory, the story / history which is put into the whole of a painting." By 1778 he extends this account to sculpture as well. Thus in the *Plastic* of 1778 he abandons the merely sensualistic conception of sculpture that dominated the *Critical Forests* and instead argues that sculpture is essentially expressive of, and therefore needs to be interpreted by, a *soul*, but this no longer forces him into unfaithfulness to his principle that thought is dependent on, and bounded by, language, for he now conceives the thoughts expressed by sculpture to have a linguistic source: "The sculptor stands in the dark of night and gropes towards the forms of gods. *The stories of the poets are before and in him*." Subsequently, in the *Theological Letters* (1780-1) and the *Letters for the Advancement of Humanity*, Herder extends the same solution to music as well.

Herder also in his considered position implies that "non-linguistic" art is dependent on thought and language in another way: In the fourth part of the *Critical Forests* he develops the point (mentioned earlier) that human perception is of its nature infused with concepts and beliefs, and consequently with language -- which of course implies that the same is true of the perception of "non-linguistic" artworks in particular. So "non-linguistic" art is really doubly dependent on thought and language: not only for the thoughts which it *expresses* but also for those which it *presupposes* in perception.

With Herder's achievement of this refined form of narrow expressivism and Hamann's articulation of broad expressivism, there were two plausible but competing theories available. Nineteenth-century theorists (e.g. Hegel, Schleiermacher, and Dilthey) would subsequently be deeply torn between them, and the dispute remains a live and important one today.

Because for Herder thought and language play important roles not only in linguistic but also in "non-linguistic" art, both for him present similar interpretive challenges, requiring similar interpretive solutions. One aspect of this which deserves special emphasis is *genre*.

Herder believes, plausibly, that a work of art is always written or made to exemplify a certain genre, and that it is vital for the interpreter to identify its genre in order to understand it. Herder's basic conception of genre is that it consists in an overall purpose together with certain rules of composition dictated thereby. For Herder, genres are in large measure socially pregiven, but they always play their role in a work via authorial intention (not autonomously thereof), and are not something the individual artist is inexorably locked into but something he can and often does modify.

Why does Herder believe that it is vital to define a work's genre-conception correctly in order to understand the work properly? He has two main reasons (both good ones): First, because an author intends his work to exemplify a certain genre, there will normally be aspects of his meaning in the work which are expressed, not explicitly in any particular part or parts of it, but rather through its intended

exemplification of the genre. For instance, Lessing had argued that the function of Aesop's fables as a genre was to illustrate through a concrete example a universal moral principle, whereas Herder argues that it was rather to illustrate general rules of life, experience, or prudence -- so the full interpretation of any particular fable must include either a universal moral principle (if Lessing is right) or a general rule of life, etc. (if Herder is right). Or to cite a "non-linguistic" case, Herder argues that Egyptian sculpture (unlike Greek) had a function as a genre of expressing certain ideas about death and eternity -- so that the full interpretation of a piece of Egyptian sculpture must include this aspect of meaning deriving from the general genre. Second, correctly identifying the genre is also vitally important for correctly interpreting things which *are* expressed explicitly in parts of a work. Hence, for example, in the *Critical Forests* Herder argues that in order to achieve a proper understanding of "ridiculous" passages in Homer (such as the Thersites episode in *Iliad*, book 2) it is essential to understand them in light of the nature of the whole text and their contribution thereto.

Just as Herder insists on a scrupulous methodological empiricism in interpretation generally, so he insists on it in connection with defining genres in particular. He therefore sharply rejects apriorism here -- both the absolute apriorism of refusing in one's definition of a genre to be guided by the observation of examples at all, and the more seductive relative apriorism of allowing oneself to be guided by the observation of examples but excluding from these particular cases, or even whole classes of cases, to which the resulting genre-conception is to be applied in interpretation. The latter procedure is still disastrous, in Herder's view, because the superficial appearance of a similar genre shared by different historical periods or cultures, or even by different authors within one period and culture, or even by a single author in one work and the same author in another, usually masks vitally important differences. Herder identifies a misguided apriorism in the definition of genres in many areas of interpretation. For example, the essay *Shakespeare* (1773) finds it in the French critics' approach to tragedy, an approach which assumes the universal validity of Aristotelian genre-rules which were originally derived exclusively from ancient tragedies (sometimes even overlooking this empirical derivation), and consequently assumes that they provide an appropriate yardstick for interpreting Shakespearean tragedy, whose genre-conception is in fact quite different. And *This Too* and other pieces find it in Winckelmann's treatment of Egyptian sculpture: Winckelmann implicitly assumes the universal validity of a genre-conception for sculpture which he has derived from the Greeks, namely one dominated by the genre-purpose of a this-worldly portrayal of life and beauty, and he then applies this in the interpretation of Egyptian sculpture, where the genre-conception is in fact quite different, in particular involving a contrary genre-purpose of conveying ideas of death and eternity.

Moreover, Herder stresses that getting questions of genre right is vitally important not only for the correct *interpretation* of artworks, but also for their correct critical *evaluation*. The French critics not only make an *interpretive* mistake when they go to Shakespeare with a genre dogmatically in mind that was not his, but they also, on this basis, make an *evaluative* one: because they falsely assume that he somehow must be aspiring to realize the genre-purpose and -rules which Aristotle found in ancient tragedy, they fault him for failing to realize them, while at the same time they overlook the quite different genre-purpose and -rules to which he really aspires and his success in realizing these. Similarly, Winckelmann not only makes an *interpretive* mistake when he implicitly imputes to the Egyptians a Greek genre-purpose and -rules for sculpture that were not theirs, but he also, on this basis, makes an

evaluative one: because he falsely assumes that the Egyptians somehow must be aspiring to realize the Greek genre-purpose and -rules, he faults them for failing to realize them, and at the same time he overlooks their success in realizing the very different genre-purpose and -rules which they really do aspire to realize.

Nothing has yet been said about *beauty*, which philosophers often think of as the central concern of the philosophy of art. Herder strikingly, and plausibly, argues that, on the contrary, beauty is not nearly as essential to art as it is often taken to be. He makes this point in the *Calligone*, for example, where he argues that art is much more essentially a matter of *Bildung* -- i.e., roughly, cultural formation or education (especially in moral respects).

A further claim which he makes about beauty (both in art and more generally) is that standards of beauty vary greatly from one historical period and culture to another. This is his usual position, from early works such as *On the Change of Taste* to late works such as *Calligone* (where he invokes it against Kant's *Critique of Judgment*). There is also an occasional counterstrand in which he argues for a deeper unity in standards of beauty across historical periods and cultures (e.g. in the *Critical Forests*). However, the former position is his considered one, and seems much the more plausible one.

Finally, in close connection with the point mentioned above that the fundamental role of the arts is one of *Bildung*, Herder in *On the Effect of Poetic Art on the Ethics of Peoples in Ancient and Modern Times* (1778) and in *Calligone* argues more specifically that the fundamental role of the arts both has been historically and moreover should be one of moral character formation.

Herder has a fairly nuanced account of how the arts do and should perform this function. For example, *On the Influence of the Beautiful Sciences on the Higher Sciences* (1781) specifies three ways in which poetry and literature promote moral character formation: First, they do so "through light rules," in other words through conveying ethical principles in explicit or implicit ways. Second, and more important, they do so by presenting in an attractive light good moral examples for people to emulate: "still better, through good examples." Third, they also convey a broad range of practical experience relevant to the formation of moral character which would otherwise have to be acquired, if at all, by the more arduous route of first-hand experience. In *Calligone* Herder also notes the power that music has to affect moral character for good or ill depending on the principles with which it is associated, and the power of visual art to make moral ideals attractive by presenting them blended with physical beauty.

Herder's conception that it should be the primary function of art to form moral character also serves him as a criterion for evaluating artworks. Thus when he observes in *On the Effect* that in contrast to earlier poetry modern poetry has typically lost this function, he means this as a serious criticism of modern poetry. He even applies this criterion as a ground for criticizing certain works by his friends Goethe and Schiller which he considers amoral or immoral in content.

7. Philosophy of History

Herder's philosophy of history appears mainly in two works, *This Too* and the later *Ideas*. His fundamental achievement in this area lies in his development of the thesis mentioned earlier -- contradicting such Enlightenment philosopher-historians as Hume and Voltaire -- that there exist radical mental differences between historical periods, that people's concepts, beliefs, sensations, etc. differ in important ways from one period to another. This thesis is already prominent in *On the Change of Taste* (1766). It had an enormous influence on successors such as Hegel and Nietzsche.

Herder makes the empirical exploration of the realm of mental diversity posited by this thesis the very core of the discipline of history. For, as has often been noted, he takes little interest in the so-called "great" political and military deeds and events of history, focusing instead on the "innerness" of history's participants. This choice is deliberate and self-conscious. Because of it, *psychology and interpretation* inevitably take center-stage in the discipline of history for Herder.

Herder has deep philosophical reasons for this choice, and hence for assigning psychology and interpretation a central role in history. To begin with, he has *negative* reasons directed against traditional political-military history. Why *should* history focus on the "great" political and military deeds and events of the past? There are several possible answers: (1) A first would be that they are fascinating or morally edifying. But Herder will not accept this. For one thing, he denies that mere fascination or curiosity is a sufficiently serious motive for doing history. For another, his antiauthoritarianism, antimilitarism, and borderless humanitarianism cause him to find the acts of political domination, war, and empire which make up the vast bulk of these "great" deeds and events not morally edifying but morally *repugnant*.

This leaves two other types of motivation which might be appealed to for doing the sort of history in question: (2) because examining the course of such deeds and events reveals some sort of overall *meaning* in history, or (3) because it leads to *efficient causal insights which enable us to explain the past and perhaps also predict or control the future*. Herder is again skeptical about these rationales, however. This skepticism is clearest in the *Older Critical Forestlet* (1767-8) where, in criticism of rationale (2), he consigns the task of "the whole ordering together of many occurrences into a plan" not to the historian but to the "creator, . . . painter, and artist," and in criticism of rationale (3), he goes as far as to assert (on the basis of a Hume- and Kant-influenced general skepticism about causal knowledge) that with the search for efficient causes in history "historical seeing stops and prophecy begins." His later writings depart from this early position in some obvious ways, but also in less obvious ways remain faithful to it. They by no means *officially* stay loyal to the view that history has no discernible meaning; famously, *This Too* insists that history does have an overall purpose, and that this fact (though not the *nature* of the purpose) is discernible from the cumulative way in which cultures have built upon one another, and the *Ideas* then tells a long story to the effect that history's purpose consists in its steady realization of "humanity" and "reason." However, Herder clearly still harbors grave doubts just below the surface. This is visible in *This Too* from the work's ironically self-deprecating title; Pyrrhonian-spirited motto; vacillations between several incompatible models of history's direction (progressive?, progressive and cyclical?, merely cyclical?, even regressive?); and morbid dwelling on, and unpersuasive attempt to rebut, the "skeptical" view of history as meaningless "Penelope-work." (A few years later Herder would write that history is "a textbook of the nullity of all human things.") It is also visible in the *Ideas* from the fact that Herder's official account of the purposiveness of history gets contradicted by passages which

insist on the *inappropriateness* of teleological (as contrasted with efficient causal) explanations in history. Herder's official position certainly had a powerful influence on some successors (especially Hegel), but it is this quieter counterstrand of skepticism that represents his better philosophical judgment. Concerning efficient causal insights, Herder's later works again in a sense stay faithful to his skeptical position in the *Older Critical Forestlet* -- but they also modify it, and this time for the better philosophically speaking. The mature Herder does not, like the Herder of that work, rest his case on a *general* skepticism about the role or discernibility of efficient causation in history. On the contrary, he insists that history *is* governed by efficient causation and that we should try to discover as far as possible the specific ways in which it is so. But he remains highly skeptical about the *extent* to which such an undertaking can be successful, and hence about how far it can take us towards real explanations of the past, and towards predicting or controlling the future. His main reason for this skepticism is that major historical deeds and events are not the products of some one or few readily identifiable causal factors (as political and military historians tend to assume), but rather of chance confluences of huge numbers of different causal factors, many of which, moreover, are individually unknown and unknowable by the historian (e.g. because in themselves too trivial to have been recorded, or, in the case of psychological factors, because the historical agent failed to make them public, deliberately misrepresented them, or was himself unaware of them due to the hidden depths of his mind).

Complementing this *negative* case against the claims of traditional political-military history to be of overriding importance, Herder also has *positive* reasons for focusing instead on the "innerness" of human life in history. One reason is certainly just the sheer interest of this subject-matter -- though, as was mentioned, that would not be a sufficient reason in his eyes. Another reason is that his discovery of radical diversity in human mentality has shown there to be a much broader, less explored, and more intellectually challenging field for investigation here than previous generations of historians have realized. Two further reasons are moral in nature: (1) He believes, and plausibly so, that studying people's minds through their literature, visual art, etc. generally exposes one to them at their moral best (in sharp contrast to studying their political-military history), so that there are benefits of moral edification to be gleaned here. (2) He has cosmopolitan and egalitarian moral motives for studying people's minds through their literature, visual art, etc.: (in sharp contrast to studying unedifying and elite-focused political-military history) this promises to enhance our sympathies for peoples and for peoples at all social levels, including lower ones. Finally, doing "inner" history is also an important instrument for our *non*-moral self-improvement: (1) It serves to enhance our self-understanding. One reason for this is that it is by, and only by, contrasting one's own outlook with the outlooks of other peoples that one recognizes what is universal and invariant in it and what by contrast distinctive and variable. Another very important reason is that in order fully to understand one's own outlook one needs to identify its origins and how they developed into it (this is Herder's famous "genetic method," which subsequently became fundamental to the work of Hegel, Nietzsche, and Foucault). (2) Herder believes that an accurate investigation of the (non-moral) ideals of past ages can serve to enrich our own ideals and happiness. This motive finds broad application in Herder. An example is his exploration of past literatures in the *Fragments* largely with a view to drawing from them lessons about how better to develop modern German literature.

Herder's decision to focus on the "innerness" of history's participants, and his consequent emphasis on

psychology and interpretation as historical methods, strikingly anticipated and influenced Dilthey. So too did Herder's rationale for this, as described above, which is indeed arguably superior to Dilthey's, especially on its positive side.

Finally, Herder is also impressive for having recognized, and, though not solved, at least grappled with, a problem that flows from his picture of history (and intercultural comparisons) as an arena of deep variations in human mentality. This is the problem of *skepticism*. He tends to run together *two* problems here: (1) the problem of whether there is any *meaning* to the seemingly endless and bewildering series of changes from epoch to epoch (or culture to culture); (2) the problem that the multiplication of conflicting viewpoints on virtually all subjects that is found in history (or in intercultural comparisons) causes, or at least exacerbates, the ancient skeptic's difficulty of unresolvable disputes forcing one to suspend belief on virtually all subjects. Problem (1) has been discussed. Here it is problem (2) that concerns us. This is a problem that Troeltsch would make much of in the twentieth century. But Herder had already clearly seen it.

Herder is determined to avoid this sort of skepticism. He has two main strategies for doing so, but they are inconsistent with each other, and neither in the end works: His first is to try to defuse the problem at source by arguing that, on closer inspection, there is much more common ground between different periods and cultures than it allows. This strategy plays a central role in the *Ideas*, where in particular "humanity" is presented as a shared ethical value; and it is also present in the *Critical Forests*, where (as mentioned earlier) Herder argues that standards of beauty have an underlying unity. Herder's second strategy is rather to acknowledge the problem fully and to respond with relativism: especially in *This Too* he argues that -- at least where questions of moral, aesthetic, and prudential value are concerned -- the different positions taken by different periods and cultures are equally valid, namely for the periods and cultures to which they belong, and that there can be no question of any preferential ranking between them. The later *Letters* vacillates between these two strategies.

Neither of these strategies is satisfactory in the end. The first, that of asserting deep commonalities, is hopeless (notwithstanding its seemingly eternal appeal to empirically underinformed Anglophone philosophers). It flies in the face of the empirical evidence -- e.g. Herder in this mode sentimentally praises Homer for his "humanity," and thereby lays himself open to Nietzsche's just retort in *Homer's Contest* that what is striking about Homer and his culture is rather their *cruelty*. Moreover, it flies in the face of Herder's own better interpretive judgments about the empirical evidence -- e.g. his observation in *On the Change of Taste* that basic values have not only changed through history but in certain cases actually been inverted (an observation which strikingly anticipates a brilliant insight of Nietzsche's concerning an inversion of ethical values that occurred in antiquity).

Herder's alternative, relativist, strategy, is more interesting, but is not in the end satisfactory either (even concerning values, where its prospects seem best). There are several potential problems with it. One, which is of historical interest but probably not in the end fatal, is this: Hegel in the *Phenomenology of Spirit* and then Nietzsche in his treatment of Christian moral values saw the possibility that one might accept Herder's insight that there were basic differences in values but nonetheless avoid his relativism by subjecting others' values to an *internal* critique, a demonstration that they were internally inconsistent.

For example, Nietzsche (whose version of this idea is the more plausible) traced back such Christian values as forgiveness to a contrary underlying motive of resentment [ressentiment]. However, in order to work, such a response would need to show that the inconsistency was *essential* to the values in question, not merely something contingent that could disappear leaving the values consistently held -- and this it probably cannot do. A more serious problem with the strategy is rather a twofold one, which Nietzsche again saw: First, we cannot in fact sustain such a relativist indifference vis-à-vis others' values. Do we, for example, *really* think that a moral rule requiring the forcible burning of dead men's wives is no better and no worse than one forbidding it? Second, nor does the phenomenon of fundamental value variations *require* us to adopt such an indifference. For, while it may indeed show there to be no universal values, it leaves us with a better alternative to indifference: continuing to hold our values and to judge others' values in light of them *only now in a self-consciously non-universal way*. (As Nietzsche puts it, "My judgment is *my* judgment." Or if we reject Nietzsche's extreme individualism, "Our judgment is *our* judgment," for some less-than-universal *us*.)

8. Political Philosophy

Herder is not usually thought of as a political philosopher. But he was one, and moreover one whose political ideals are more admirable, theoretical stances more defensible, and thematic focus of more enduring relevance than those of any other German philosopher of the period. His most developed treatment of political philosophy occurs late, in a work prompted by the French Revolution of 1789: the *Letters* (including the early draft of 1792, important for its frank statement of his views about domestic politics).

What are the main features of Herder's political philosophy? We should begin with his political *ideals*, first in domestic and then in international politics: In domestic politics, the mature Herder is a liberal, a republican, a democrat, and an egalitarian (this in circumstances where such positions were by no means commonplace, and were embraced at a personal cost). His *liberalism* is especially radical in advocating virtually unrestricted freedom of thought and expression (including freedom of worship). He has several reasons for this position: (1) He feels that such freedom belongs to people's moral dignity. (2) He believes that it is essential for individuals' self-realization. (3) As mentioned earlier, he believes that human beings' capacities for discerning the truth are limited and that it is through, and only through, an ongoing contest between opposing viewpoints that the cause of truth gets advanced. (J.S. Mill would later borrow these considerations -- partly via intermediaries such as von Humboldt -- to form the core of his case for freedom of thought and expression in *On Liberty*.) Herder is also committed to *republicanism and democracy* (advocating a much broader franchise than Kant, for example). He has several reasons for this position, ultimately deriving from an egalitarian concern for the interests of all members of society: (1) He thinks it intrinsically right that the mass of people should share in their government, rather than having it imposed upon them. (2) He believes that this will better serve their *other* interests as well, since government *by* also tends to be government *for*. (3) He in particular believes that it will diminish the warfare that is pervasive under the prevailing autocratic political régimes of Europe, where it benefits the few rulers who decide on it but costs the mass of people dearly. Finally, Herder's *egalitarianism* also extends further. He does not reject class differences, property, or

inequalities of property outright. But he opposes all hierarchical oppression; argues that all people in society have capacities for self-realization, and must receive the opportunity to realize them; and insists that government must intervene to ensure that they do, e.g. by guaranteeing education and a minimum standard of living for the poor.

Concerning international politics, Herder often gets classified as a "nationalist" or (even worse) a "German nationalist." Some other philosophers from the period deserve this slur (e.g. Fichte). But where Herder is concerned it is deeply misleading and unjust. On the contrary, his fundamental position in international politics is a committed *cosmopolitanism*, an impartial concern for *all* human beings. This is a large part of the force of his ideal of "humanity." Hence, for example, in the *Letters* he approvingly quotes Fénelon’s remark, "I love my family more than myself; more than my family my fatherland; more than my fatherland humankind." Moreover, unlike Kant’s cosmopolitanism, Herder’s is genuine. Kant’s cosmopolitanism is vitiated by a set of empirically ignorant and morally inexcusable prejudices which he harbors -- in particular, racism, antisemitism, and misogyny. By contrast, Herder’s is entirely free of these prejudices, which he indeed works tirelessly to combat.

Herder does *also* insist on respecting, preserving, and advancing national groupings. But this is unalarming, for the following reasons: (1) For Herder, this is emphatically something that must be done for *all* national groupings *equally* (not just or especially Germany!). (2) The "nation" in question is not racial but linguistic and cultural (Herder rejects the very concept of race). (3) Nor does it involve a centralized or militaristic state (Herder advocates the disappearance of such a state and its replacement by loosely federated local governments with minimal instruments of force). (4) In addition, Herder’s insistence on respecting national groupings is accompanied by the strongest denunciations of military conflict, colonial exploitation, and all other forms of harm between nations; a demand that nations instead peacefully cooperate and compete in trade and intellectual endeavors for their mutual benefit; and a plea that they should indeed actively work to help each other.

Moreover, Herder has compelling reasons for his insistence on respecting national groupings: (1) The deep diversity of values between nations entails that homogenization is ultimately impracticable, only a fantasy. (2) Such diversity also entails that, to the extent that it *is* practicable, it cannot occur voluntarily but only through external coercion. (3) In practice, attempts to achieve it, e.g. by European colonialism, are moreover coercive from, and subserve, ulterior motives of domination and exploitation. (4) Real national variety is moreover positively valuable, both as affording individuals a vital sense of local belonging and in itself.

It might be objected that all this does not yet really amount to a political *theory* -- such as other philosophers have given, including some of Herder’s contemporaries in Germany. In a sense that is true, but philosophically defensible; in another sense it is false. It is true in this sense: There is indeed no grand metaphysical theory underpinning Herder’s position -- no Platonic theory of forms, no correlation of political institutions with "moments" in a Hegelian Logic, no "deduction" of political institutions from the nature of the self or the will à la Fichte and Hegel, etc. But that is deliberate, given Herder’s skepticism about such metaphysics. And is it not indeed philosophically a good thing? Nor does Herder have any elaborate account purporting to justify the moral intuitions at work in his political position as a

sort of theoretical insight (in the manner of Kant's theory of the "categorical imperative" or Rawls's theory of the "original position," for example). But that is again quite deliberate, given his non-cognitivism in ethics, and his rejection of such theories as both false and harmful. And is he not again right about this, and the absence of such an account therefore again a good thing? Nor is Herder sympathetic with such tired staples of political theory as the state of nature, the social contract, natural rights, the general will, and utopias for the future. But again, he has good specific reasons for skepticism about these things. This, then, is the sense in which the objection is correct; Herder does indeed lack a "political theory" of *these* sorts. But he lacks it *on principle,* and is arguably quite right to do so.

On the other hand, he *does* have a "political theory" of another, and arguably more valuable, sort. For one thing, consistently with his general empiricism, his position in political philosophy is deeply empirically informed. For instance, as can be seen from the *Dissertation on the Reciprocal Influence of Government and the Sciences* (1780), his thesis about the importance of freedom of thought and expression, and the competition between views which it makes possible, for producing intellectual progress is largely based on the historical example of ancient Greece and in particular Athens (as contrasted with societies which have lacked the freedom and competition in question). And in the 1792 draft of the *Letters* he even describes the French Revolution and its attempts to establish a modern democracy as a sort of "experiment" from which we can learn (e.g. whether democracy can be successfully extended to nations much larger than ancient Athens). For another thing, conformably with his general non-cognitivism about morals, he is acutely aware that his political position ultimately rests on moral sentiments -- his own and, for its success, other people's as well. For example, the 10th Collection of the *Letters* stresses the fundamental role of moral "dispositions" or "feelings" as required supports for his political position's realization. As was mentioned, this standpoint absolves him of the need to do certain sorts of theorizing. However, it also leads him to engage in theorizing of another sort, namely theorizing about how, and by what means, people's moral sentiments should be molded in order to realize the ideals of his political position. His discussion of moral "dispositions" in the 10th Collection is an example of such theorizing (concerning the *how* rather than the means; his theorizing about causal means has been sketched earlier in this article). *These* two sorts of theorizing *are* deeply developed in Herder. And they are arguably much more pointful than the sorts which are not.

In short, to the extent that Herder's political philosophy really is theoretically superficial, it is arguably, to borrow a phrase of Nietzsche's, "superficial -- *out of profundity*" (whereas more familiar forms of political philosophy are profound out of superficiality). And in another, more important, sense it is not theoretically superficial at all.

9. Philosophy of Religion

In Herder's day German philosophy was deeply committed to a game of trying to reconcile the insights of the Enlightenment, especially those of modern science, with religion, and indeed with Christianity. Leibniz, Kant, Hegel, Schleiermacher, and many others played this game -- each proposing some new reconciliation or other. Herder was part of this game as well. This was not a good game for philosophers to be playing. But it was only in the nineteenth century that German philosophy found the courage to cut

the Gordian knot and turn from apologetics for religion and Christianity to thoroughgoing criticism of them (prime examples being Marx and Nietzsche). This situation imposes limits on the interest of Herder's philosophy of religion, as on that of the other reconciling philosophers mentioned.

Also, while Herder's philosophy of religion was extremely enlightened and progressive in both his early and his late periods, there was a spell in the middle, the years 1771-6 in Bückeburg, during which he fell into the sort of religious irrationalism more characteristic of his friend Hamann. This happened as the result of what we would today classify as a mild nervous breakdown (documentable from his correspondence at the time), and should be discounted.

Despite these qualifications, Herder did make important contributions to the philosophy of religion -- i.e. important in terms of their influence, their intrinsic value, or both. One of these (important for its influence) is his neo-Spinozism, expounded in *God. Some Conversations* of 1787. In this work he develops a version of "Spinozism" which consciously modifies the original in important respects. He shares with Spinoza the basic thesis of *monism*, and like Spinoza equates the single, all-encompassing principle in question with God. But whereas Spinoza characterized it as *substance*, Herder prefers to characterize it as *force*, or *primal force*. Moreover, this modification involves further ones which Herder finds attractive, including: (1) Spinoza's theory had rejected conceptions of God as a mind, as a being who thinks or has purposes. Given Herder's general philosophy of mind and its identification of the mind with force, his identification of God with force imports a claim that God *is* in fact a mind -- hence in works such as *On the Spirit of Christianity* (1798) he describes God as a *Geist*, a mind or spirit. Accordingly, Herder claims that God *does* think, and even have purposes. (2) Herder believes that Spinoza's original theory contains a residue of objectionable dualism, inherited from Descartes, in its conception of the relation between God's two known attributes, thought and extension (and similarly, in its conception of the relation between finite minds and bodies). By contrast, the conception of God as a force (and of finite minds as likewise forces) overcomes this residual dualism. For forces are of their very nature expressed in extended bodies. From around the time of *God. Some Conversations* until well into the nineteenth century a wave of neo-Spinozism swept through German philosophy: Goethe, Schelling, Hegel, Schleiermacher, and lesser figures such as Hölderlin, Novalis, and F. Schlegel. This wave was mainly the result of Herder's embrace of neo-Spinozism in that work, and took over his modifications of Spinoza's position.

However, Herder's most intrinsically valuable contribution to the philosophy of religion concerns the interpretation of the bible. In this connection, as previously mentioned, he champions a strict *secularism*. This was already his position in the 1760's. At that period he argued vigorously, in the spirit of Galileo, for disallowing revelation any jurisdiction over natural science -- though he did so not in an anti-religious spirit but in the hope and expectation that an autonomous natural science would confirm religion. And he made a parallel case for the autonomy of *interpretation*: Religious assumptions and means have no business interfering in the interpretation of texts either, even when the texts are sacred ones. Instead, biblical texts must be interpreted as the works of human beings, and by means of the same sorts of rigorous hermeneutical methods that are employed for interpreting other ancient texts -- any religious enlightenment coming as a *result* of such interpretation, not entering into the process itself. This whole position remained Herder's considered stance in his later period as well.

The general idea that the bible should be interpreted in the same way as other texts was by no means the commonplace in Herder’s day that it has since become, but nor was it new with him. In adopting this principle he was self-consciously following the lead of several recent bible scholars -- in particular, Ernesti, Michaelis, and Semler. However, Herder’s secularism is more consistent and radical than theirs.

This can be illustrated by a comparison with Ernesti (the most important of the scholars just mentioned, and the one most consistently admired by Herder). Ernesti’s great work, *Institutio interpretis Novi Testamenti* (1761), which Herder singles out for special praise, is a key statement of the sort of secularism in question. Initially, this work seems to advocate a secularism identical in spirit to Herder’s, arguing that we must interpret biblical books in the same way as profane texts, and *thereby* learn whatever religious truth they contain. However, as the work develops, matters become much cloudier. In this connection, it is important to distinguish two questions which can be asked concerning divine inspiration and interpretation: (1) May readers of sacred texts rely on a divine inspiration of *themselves* (e.g. by the Holy Spirit) bringing them to a correct interpretation rather than on more usual interpretive means? (2) May they assume in interpretation that because *the texts’ authors* are divinely inspired the texts must be completely true and therefore also (a fortiori) completely self-consistent? When Ernesti develops the details of his position it becomes clear that he has really only advanced as far towards secularism as consistently answering question (1) in the negative, *not question (2)*. His failure to give a consistently negative answer to question (2) lands him in flat contradiction with his official commitment to interpreting sacred texts in exactly the same way as profane texts (for of course, as he indeed himself implies, in interpreting profane texts we may *not* assume that the texts are throughout true and therefore also self-consistent). It also seems intellectually indefensible in itself -- merely a rather transparent refusal to stop, so to speak, "cooking the books" in favor of the bible when interpreting it. By contrast, the young Herder advances in his secularism beyond Ernesti because he consistently answers *both* questions in the negative, and thereby, unlike Ernesti, achieves a position which is both self-consistent and otherwise intellectually defensible. Moreover, Herder’s actual interpretations of the bible admirably conform to this theoretical position, not only refraining from any reliance on divine inspiration and instead employing normal interpretive techniques, but also frequently attributing false and even inconsistent positions to the bible (both to the Old and to the New Testaments).

Another noteworthy feature of Herder’s secularism is his insistence that interpreters of the bible must resist the temptation to read the bible as *allegory* (except in those few cases -- e.g. the parables of the New Testament -- where there is clear textual evidence of a biblical author’s intention to convey an allegorical meaning). Herder gives a perceptive general diagnosis of the temptation to allegorical interpretation: over the course of history people’s beliefs and values change, leading to discrepancies between the claims made by their traditional texts and their own beliefs and values, but they expect and want to find their traditional texts correct, and so they try to effect a reconciliation with their own beliefs and values by means of allegorical readings.

Herder’s theoretical commitment to strict secularism in biblical interpretation led him to interpretive discoveries concerning the bible which were in themselves of epoch-making importance. For example, concerning the Old Testament, his commitment to applying normal hermeneutical methods enabled him

to distinguish and define the different genres of poetry in the Old Testament in a way that was superior to anything done before him. Also, that commitment, and in particular his consequent readiness to find falsehood and even inconsistency in the bible, allowed him to make such important interpretive observations as that the ancient Jews' conceptions about death, afterlife, mind, and body, had changed dramatically over time. (For these two achievements, see especially *On the Spirit of Hebrew Poetry*.) Again, that commitment, and in particular Herder's consequent rejection of unwarranted allegorical interpretations, allowed him to substitute for the prevailing interpretation of the *Song of Solomon* as religious allegory an interpretation of it as simple erotic love poetry which is today generally accepted as correct. Similarly concerning the New Testament, Herder's commitment to applying normal hermeneutical methods, including his consequent readiness to recognize falsehood and inconsistency, enabled him to treat the authors of the four gospels as individual human authors instead of as mere mouthpieces of the deity, to perceive inconsistencies between their accounts, to establish the relative dates of the gospels correctly for the first time (Mark first, Matthew and Luke in the middle, John last and late), and to give a broadly correct account of their genesis in oral sermon and their likely relations to each other -- achievements attained above all in two late works from 1796-97, *On the Savior of Mankind* and *On God's Son, the World's Savior*.

Herder's strict secularism in interpretation would later be replicated by Schleiermacher, who similarly embraces the principle that the interpretation of sacred texts must treat them as the works of human authors and by means of exactly the same interpretive methods as are applied to profane texts, and similarly follows through on this commitment, in particular finding not only falsehoods but also inconsistencies in the bible.

Herder's achievements in this area have something of the character of the early acts of an inexorable tragedy, however. As was mentioned, he by no means intended his championing of the cause of intellectual conscience in insisting on the autonomy of natural science and interpretation to undermine religion in general or Christianity in particular; on the contrary, his hope and expectation was that both sorts of autonomy would in the end support religion and Christianity. However, this hope has been sorely disappointed. Autonomous natural science has increasingly made religion generally and Christianity in particular look untenable. And Herder's policy of reading the bible as a collection of human texts, with all the foibles of human texts, has increasingly led to an undermining of the bible's claims to intellectual authority. Much of what Herder has ultimately achieved in this area would therefore be deeply unwelcome to him.

Bibliography

Primary Texts

There are two main German editions of Herder's works:

- *Johann Gottfried Herder Sämtliche Werke*, B. Suphan, *et al*. (eds.), Berlin, 1887-.

- *Johann Gottfried Herder Werke*, U. Gaier, *et al*. (eds.), Frankfurt am Main, 1985-.

The latter edition includes very helpful notes.

Translations

- Adler, H., and Menze, E.A., *On World History,* Armonk, 1996.
  (Contains short excerpts on history from a variety of works, prominently including the *Ideas*.)
- Barnard, F.M., *J.G. Herder on Social and Political Culture*, Cambridge, 1969.
  (Includes (partial) translations of Herder's 1769 *Journal*, *On the Origin*, *This Too*, the *Dissertation on the Reciprocal Influence of Government and the Sciences*, and the *Ideas*, plus a very good introduction.)
- Burkhardt, F.H., *God. Some Conversations*, New York, 1940.
- Churchill, T., *Outlines of a Philosophy of the History of Man*, London, 1800.
  (A translation of the *Ideas*.)
- Forster, M.N., *J.G. Herder: Philosophical Writings*, Cambridge, 2001/2.
  (Contains full translations of *How Philosophy, On the Origin*, *On the Cognition*, and *This Too*, as well as other pieces.)
- Marsh, J., *The Spirit of Hebrew Poetry*, Burlington, Vt., 1833.
- Menze, E.A., Menges, K., and Palma, M., *Johann Gottfried Herder: Selected Early Works, 1764-7*, Pennsylvania, 1992.
  (Contains some early essays and selections from the *Fragments*.)
- Moran, J.H., and Gode, A., *On the Origin of Language*, Chicago, 1986.
  (Contains a partial translation of *On the Origin*.)
- Nisbet, H.B., *German Aesthetics and Literary Criticism: Winckelmann, Lessing, Hamann, Herder, Schiller, Goethe*, Cambridge, 1985.
  (Contains two pieces of Herder's in aesthetics, including his important essay *Shakespeare*.)

Secondary Literature in German

By far the most helpful single item remains:

- Haym, R., *Herder nach seinem Leben und seinen Werken*, Berlin, 1880.
  (A classic, detailed intellectual biography.)

Two useful recent collections of essays covering a broad range of topics are:

- Sauder, G. (ed.), *Johann Gottfried Herder 1744-1803*, Hamburg, 1987.
- Bollacher, M. (ed.), *Johann Gottfried Herder: Geschichte und Kultur*, Würzburg, 1994.

H.D. Irmischer has written several important articles on topics covered here, including:

- Irmischer, H., "Grundzüge der Hermeneutik Herders," in *Bückeburger Gespräche über J.G. Herder 1971*, Bückeburg, 1973.
- Irmischer, H., "Grundfragen der Geschichtsphilosophie Herders bis 1774," in *Bückeburger Gespräche über J.G. Herder 1983*, Bückeburg, 1984.

A helpful treatment of Herder’s interest in world literature, and in particular his theory and practice of translation, is:

- Kelletat, A.F., *Herder und die Weltliteratur*, Frankfurt am Main, 1984.

A good treatment of Herder’s approach to the Old Testament:

- Willi, T., *Herders Beitrag zum Verstehen des Alten Testaments*, Tübingen, 1971.

Secondary Literature in English

General treatments:

- Berlin, I., *Vico and Herder*, New York, 1976.
  (Concise and excellent.)
- Clark Jr., R.T., *Herder: His Life and Thought*, Berkeley, 1955.
  (Detailed and useful but unimaginative.)
- Beiser, F.C., *The Fate of Reason*, Cambridge, Mass., 1987.
  (Ch. 5 covers several topics helpfully, including Herder’s philosophies of language, mind, and religion.)

Herder’s general program and debts to the precritical Kant:

- Zammito, J.H., *Kant, Herder, and the Birth of Anthropology*, Chicago, 2001.

Philosophy of language:

- Forster, M. N., "Herder’s Philosophy of Language, Interpretation, and Translation: Three Fundamental Principles," forthcoming. *The Review of Metaphysics*.
- Taylor, C., "The Importance of Herder," in E. and A. Margalit eds., *Isaiah Berlin: A Celebration*, Chicago, 1991.
- Taylor, C., "Language and Human Nature," in C. Taylor, *Human Agency and Language: Philosophical Papers 1*, Cambridge, 1996.

Aesthetics:

- Norton, R.E., *Herder's Aesthetics and the European Enlightenment*, Ithaca, 1991.
  (Helpful both on aspects of Herder's aesthetic theory and on Herder's general relation to the Enlightenment.)

Philosophy of history:

- Lovejoy, A.O., "Herder and the Enlightenment Philosophy of History," in *Essays on the History of Ideas*, Baltimore, 1948.
  (A helpful short treatment.)
- Meinecke, F., *Historism: The Rise of a New Historical Outlook*, London, 1972.
  (Ch. 9 is very helpful.)

Political Philosophy:

- Ergang, R., *Herder and the Foundations of German Nationalism*, New York, 1931.
  (Helpful both on Herder's political thought and on his general intellectual influence.)
- Barnard, F.M., *Herder's Social and Political Thought: From Enlightenment to Nationalism*, Oxford, 1965.
  (Chs. 3-5 deal with Herder's political thought.)
- Beiser, F.C., *Enlightenment, Revolution, and Romanticism*, Cambridge, Mass., 1992.
  (Ch. 8 on Herder's political philosophy is excellent.)

Other Subjects:

- Nisbet, H.B., *Herder and the Philosophy and History of Science*, Cambridge, Mass., 1970.
  (An excellent account of Herder's stance towards science.)

Johann Georg Hamann

Johann Georg Hamann (1730-1788) lived and worked in Prussia, in the context of the late German Enlightenment. Although he remained outside 'professional' philosophical circles, in that he never held a University post, he was respected in his time for his scholarship and breadth of learning. His writings were notorious even in his own time for the challenges they threw down to the reader. These challenges to interpretation and understanding are only heightened today.

Nevertheless an increasing number of scholars from philosophy, theology, aesthetics and German studies are finding his ideas and insights of value to contemporary concerns. His central preoccupations are still pertinent: language, knowledge, the nature of the human person, sexuality and gender and the relationship of humanity to God. Meanwhile, his views, which in many respects anticipate later challenges to the Enlightenment project and to modernity, are still relevant and even provocative.

---

1. Life

Johann Georg Hamann was born in Königsberg in 1730, the son of a midwife and a barber-surgeon. He

began study in philosophy and theology at the age of 16, changed to law but mainly read literature, philology, and rhetoric, but also mathematics and science. He left university without completing his studies and became the governor to a wealthy family on a Baltic estate. During this time he continued his extraordinarily broad reading and private research. He took up a job in the family firm of a friend from his Königsberg days, Christoph Berens, and was sent on an obscure mission to London, in which he evidently failed. He then led a high life until he ran out of friends, money and support. In a garret, depressed and impoverished, he read the Bible cover to cover and experienced a religious conversion.

He returned to the House of Berens in Riga, where they evidently forgave him his failure. He fell in love with Christoph Berens' sister, Katharina, but was refused permission to marry her by his friend, on the grounds of his religious conversion; Berens was an enthusiastic follower of the Enlightenment and was nauseated by the more pious manifestations of Hamann's new-found religiosity. Smarting from this blow and its motivations, Hamann returned to his father's house in Königsberg, where he lived for the rest of his life until his final months.

In Königsberg, he never held an official academic post, nor an ecclesiastical one; this may in part have been due to his pronounced speech impediment, which inhibited him from either lecturing or preaching. Eventually, through the intercession of his acquaintance, Immanuel Kant, he found employment as a low-level civil servant working in the tax office of Frederick the Great; a ruler Hamann in fact despised. Nevertheless his principal activity was as an editor and a writer; he was considered one of the most widely-read scholars of his time (greatly aided by his fluency in many languages), as well as a notorious author. During this time, despite his committed Christianity, he lived with a woman whom he never married but to whom he remained devoted and faithful, having four children on whom he doted, and who occasionally feature in his writings (principally as unruly distractions to the author's scholarship).

At the end of his life he accepted an invitation to Münster from one of his admirers, Princess Gallitzin. He died in Münster in 1788.

Hamann had a profound influence on the German ‘Storm and Stress’ movement, and on other contemporaries such as Herder and Jacobi; he impressed Hegel and Goethe (who called him the brightest head of his time) and was a major influence on Kierkegaard. His influence continued on twentieth century German thinkers, particularly those interested in language. His popularity has increased dramatically in the last few decades amongst philosophers, theologians, and German studies scholars around the world.

2. Writings

Hamann's writings are all short; he was not given to extensive treatises. They are also usually motivated by something very specific: someone else's publication, or particular circumstances and events. When responding to these, he presupposes considerable knowledge on the part of the reader; typically his responses to the work of others involves adoption of their terminology and style, blending into mimicry and parody as a rhetorical and argumentative device. Moreover, woven into these writings is an extraordinary breadth and quantity of citations and allusions; and by no means are these all clear and

obvious. Thus, when he chooses, his essays are a tapestry of multicolored threads of the ideas, language, and imagery of thinkers, be they ancient, biblical, or contemporary. These are woven across a woof of a love of irony, which as ever adds a layer of interpretative complexity.

Hamann's writings also frequently appear under the name of various fanciful characters: Aristobolus, the Knight of the Rose-Cross, the Sibyl, Adelgunde. It cannot be assumed that such characters faithfully represent Hamann's own views; The opinions of Aristobolus, for example, are a device to deconstruct and drive to absurdity a number of views which Hamann opposes.

These factors combine to make Hamann's writings notoriously difficult to understand and interpret. Goethe observed that when reading Hamann, “one must completely rule out what one normally means by understanding.” [Goethe, 550] Even if one has – or painfully acquires, or borrows from other current scholars – the breadth of reference to understand the source of an allusion or citation, it is not always clear what the citation is doing there, and what Hamann means to suggest by referring to it. He delighted in sporting with his reader; preferring to present a balled fist and leave it to the reader to unroll it into a flat hand (to borrow one of his own images; cf. the end of the “Metacritique of the Purism of Reason”, 1780.)

This impenetrability has been taken by some to signify an incapacity for clear expression on Hamann's part. Hegel remarked: "The French have a saying: *Le stile c'est l'homme meme* (“The style is the man himself”); Hamann's writings do not *have* a particular style but rather *are* style through and through." [Hegel, 209.] Others, however, have pointed to the clarity and concision of his letters, in contrast to the puzzling style he uses to address the public. They suggest that Hamann's challenging style forms are an important part of Hamann's hermeneutics and his understanding of the relationship between the writer and reader: two halves of a whole who must relate themselves to one another and unite for a common goal (“Reader and Critic”, 1762.) The reader cannot be passive and must work to reconstruct Hamann's meaning. As Hamann observed, “A writer who is in a hurry to be understood today or tomorrow runs the danger of being misunderstood the day after tomorrow.”

Consequently, Hamann is highly susceptible to misinterpretation. For example, one can find in recent English-language treatments the understanding of Hamann as an ‘irrationalist’, and one who simply opposed the Enlightenment with all his might; this however is not supported by the majority of Hamann scholars and is seen as a failure to understand the complexity of his thinking.

His principal writings include: *Biblische Betrachtungen* [Biblical Reflections], *Gedanken über meinen Lebenslauf* [Thoughts on the Course of my Life], *Brocken* [Fragments], *Sokratische Denkwürdigkeiten* [Socratic Memorabilia], *Wolken* [Clouds], *Kreuzzüge des Philologen* [Crusades of the Philologian], a collection of essays including Aesthetica in Nuce, *Versuch über eine akademische Frage* [Essay on an academic question], and *Kleeblatt Hellenistischer Briefe* [Cloverleaf of Hellenistic Letters]; *Schriftsteller und Kunstrichter* [Author and Critic], *Leser und Kunstrichter* [Reader and Critic], *Fünf Hirtenbriefe* [Five Pastoral Letters], *Des Ritters von Rosencreuz letzte Willensmeynung über den göttlichen und menschlichen Urprung der Sprache* [The Knight of the Rose-Cross' Last Will and Testament on the divine and human origin of language], *Philologische Einfälle und Zweifel* [Philological Ideas and Doubts], *Hierophantische Briefe* [Hierophantic Letters], *Versuch einer Sibylle über die Ehe* [Essay of a

Sibyl on Marriage], *Konxompax*, *Metakritik über den Purismum der Vernunft* [Metacritique of the Purism of Reason], *Golgotha und Scheblimini* [Golgotha and Scheblimini], *Fliegender Brief* [Flying Letter].

3. Metacritique

At the end of his life, Hamann chose to designate his authorship as “Metacritique”, a word he coined for his engagement with Kant's *Critique of Pure Reason*. Instead of creating a systematic theology, or an epistemology, he seems to have seen his work as one that examines the foundations and nature of philosophical and theological critique itself. Rather like the late Wittgenstein, his work was deconstructive; he belongs in the camp of philosophers whom Richard Rorty has described as “edifying and therapeutic” rather than “constructive and systematic”. (Rorty, 5-6.) He brings to any issue in philosophy not a constructive account, but an approach, a set of convictions, something akin to ethical principles. He anticipated Rorty's emphasis on the curative aspects of this task; at the end of his life, he wanted his collected works to be published under the title “Curative Baths” (“*Saalbadereyen*”&151;a reference to healing practices of the time and an allusion to his father's profession.) Each volume was to be called a ‘Tub’. This project was sadly never realized, not even under a more conventional title.

One abiding characteristic of Hamann's many responses to the philosophy of his time, therefore, is this ‘metacritical’ instinct: not to construct a rival account, but to go for the jugular; not to set up a rival critique, but to insist that critique itself must be subject to meta-critique, which concerns itself with the issues that must be attended to in relation to the act of philosophical reflection itself. It consists of attention to the fundamental stance or position on issues or insights that must underlie any work on philosophy or theology. According to Hamann, often “the difficulties lie in womb of the concepts”. (N III, 31, 21) Hamann's writing therefore is not so much ‘unsystematic’ as is sometimes said, but ‘presystematic’. He addresses issues that must be recognized in any self-critical reflection, matters that must be presuppositions for any system. Thus one of the most salient features of his “Metacritique of the Purism of Reason”, his unpublished response to Kant's *Critique of Pure Reason*, was to focus on the question of language. Through a tissue of imagery, he suggests that a proper view of language implies that the alleged ‘purity’ of *a priori* reason is untenable.

These metacritical issues, for Hamann, principally include language, knowledge, and the nature of the human person. Hamann also, most urgently and most controversially (then as now), did not believe that any of these issues can be answered outside a theological perspective; that is, without reference to God as humanity's creator and dialogue partner.

4. Relation

A second feature of Hamann's approach is a tendency which Goethe saw as holism. This is perhaps not the best way to describe Hamann's insight, as Hamann characteristically emphasised the brokenness of human experience, and fragmentariness of human knowledge: “Gaps and lacks&151;is the highest and deepest knowledge of human nature, through which we must climb our way up to the ideal—ideas and

doubts&151;the *summum bonum* of our reason.” (ZH 3, 34:33-35) Hamann essentially disliked attempts to isolate the phenomenon under consideration from other aspects with which he felt it to be intimately connected; this precludes a deep and true understanding of our existence. Taken as far as he did, this means that philosophy of language must include a discussion of God, and a discussion of God must make reference to sexuality and *vice versa*.

Thus in “Essay of a Sibyl on Marriage”, which he takes as an opportunity to write about sex, a proper understanding of human sexuality and erotic enjoyment cannot be understood without seeing humanity as the creature of God, made in God's image. He plays with the Christian idea of God as a Trinity to depict a trinity of woman-man-God in the moment of lovemaking; and reworks the account of the creation of Adam in Genesis to describe the act of coitus itself. The woman on perceiving her lover in his excitement sees ‘that rib’ and cries out in enthusiastic appropriation, ‘That is bone of my bone and flesh of my flesh!’ The man then ‘fills the hole of the place with flesh’ (as Genesis describes God doing with Adam after the creation of Eve). In doing so the lover also acknowledges that the origin of a man is in woman's body: the ‘Sibyl’ describes this moment of lovemaking as ”he entered in whence he once came forth.” Indeed, as Christ was born of a woman, the salvation of humanity proceeds from a woman's sexual body; the vagina is also described as the place that the Saviour came forth as the body's healer (the German language permits Hamann here to pun on ‘healer’ and ‘saviour’). This inclination to combine topics more often kept separate (such as ‘the concept of God’ and ‘having sex’) is salient throughout his work.

5. The Union of Opposites

Hamann's tool for conceiving the interrelation of these dimensions of human life increasingly was the Principle of the Union of Opposites. He writes approvingly of this principle to his friends; particularly after his encounter with Kant's new epistemology, claiming to value it more than the principles of contradiction and of sufficient reason, and indeed more than the whole Kantian Critique. (ZH 5, 327:12ff; ZH 4, 462:7-8) Contradictions and apparent oppositions fill our experience:

> Yes, daily at home I have the experience that one must always contradict oneself from two viewpoints, [which] never can agree, and that it is impossible to change these viewpoints into the other without doing the greatest violence to them. Our knowledge is piecemeal — no dogmatist is in a position to feel this great truth, if he is to play his role and play it well; and through a vicious circle of pure reason skepsis itself becomes dogma. (ZH 5, 432:29-36) (This is in the context of a discussion of Kant.)

Far from being a pre-condition for truth, the absence of contradiction is in Hamann's eyes a pre-condition for dogmatism. Knowledge must not proceed on the basis of unanimity and the absence of contradiction, but must proceed through the dialogue and relation of these different voices. (Hamann does not think in terms of Hegel's later dialectical synthesis.) When Hamann speaks of ‘opposition’ and contradictions, however, he does so in an ironic tone; for it is clearly his conviction that there is a fundamental unity in things, and the oppositions and contradictions that we perceive are chiefly of our own making. He insists that his perception is ‘without Manichaeism’. (ZH 5, 327:16-17) Body and mind, senses and reason,

reason and passion are not truly opposed. These are contrasting elements of the same unified – unified but not homogenous&151;reality. Hamann tries to steer a course between Scylla and Charybdis: between the dogmatic, even tyrannical extermination of opposition and contradiction; and the elimination of contradiction through a false synthesis or fusion achieved by an apparent acceptance of antithetical realities.

The Principle of the Union of Opposites as a tactical tool, therefore, does not imply that Hamann sees the world in terms of divisions and dualism. It is his strategy for coping with the schematic antitheses abundant in Enlightenment philosophy.

> Nothing seems easier than the leap from one extreme to the other, and nothing so difficult as the union to a center. … [TheUnion of Opposites] always seems to me to be the one sufficient reason of all contradictions&151;and the true process of their resolution and mediation, that makes an end to all feuds of healthy reason and pure unreason.(ZH 4, 287:5-17)

6. ‘Prosopopoeia’

Hamann used the notion of ‘Prosopopoeia’, or personification, as an image of what can happen in philosophical reflection. In a medieval morality or mystery play, the experience of being chaste or being lustful is transformed from a way of acting or feeling into a dramatic character who then speaks and acts as a personification of that quality. So too in philosophy, Hamann suggests. The philosopher distinguishes differing aspects in the phenomenon under scrutiny and exaggerates their difference. These aspects are ennobled into faculties, and through ‘prosopopoeia’ are hypostasized into entities. Thus in the act of reflecting on something, ‘reasoning’ is distinguished from ‘feeling’, and turned from a verb or gerund into a noun — ‘reason’—which is then named as a constituent of our being. Reason then becomes a thing to which we can ascribe properties. (This shows perhaps a streak bordering on nominalism in Hamann.)

The best example of this, and of Hamann's response, is his treatment of the word ‘reason’. Since he handles it with a kind of skepticism or even distaste, he is often called an ‘irrationalist’. It is clear however that Hamann puts a high value on certain ways of being reasonable and of reasoning activity. “Without *language* we would have no reason, without reason no religion, and without these three essential aspects of our nature, neither mind *[Geist]* nor bond of society”. (N III, 231, 10-12)

Hamann's treatment of reason instead is a deconstruction, both of the prosopopoeic use of the word and the Enlightenment valuation of it. There is no such thing as reason — there is only reasoning. Reasoning, as something we do, is as fallible as we are, and as such is subject to our position in history, or own personality, or the circumstances of the moment. ‘It’ is therefore not a universal, healthy and infallible ‘faculty’ as Hamann's Enlightenment contemporaries often maintained:

> *Being*, *belief and reason* are pure relations, which cannot be dealt with absolutely, and are not things but pure scholastic concepts, *signs* for understanding, not for worshipping, aids

to awaken our attention, not to fetter it. (ZH 7, 165:7-11)

7. Enlightenment

Hamann is sometimes portrayed simply as an opponent of ‘the Enlightenment’. This presupposes of course that ‘the Enlightenment’ constitutes a unified stance on a number of philosophical issues, an assumption which is questionable. The majority of Hamann scholars today see his position in a more complex way. Hamann opposed many of the popular convictions of his time. However, Hamann fought his contemporaries on many fronts; often with areas of considerable agreement with some of his opponents. One example would be the way that he deployed Hume as a weapon against Enlightenment rationalism, not least against Kant (although Hamann was the one who introduced Kant to Hume's writings in the first place). Although Hamann, as a Christian, had profound disagreements with Hume's thought in its atheistic aspects, nevertheless he used Humean skepticism in his own deconstructive writings. Hume's doubts about the reliability and self-sufficiency of reason were grist to Hamann's mill. Hume's insistence that ‘belief’ underlies much of our thinking and reasoning was adopted and deployed by Hamann, often with a linguistic sleight of hand. By using the word ‘*Glaube*’ (which in German includes both ‘belief’ in an epistemic sense and ‘faith’ in a religious sense), Hamann could assert that ‘faith’, not rational grounds, underlies his contemporaries' high valuation of reason. Thus even the enthusiastic advocates of impartiality and ‘reason’, who are also skeptics about ‘blind faith’, have ultimately only faith as the ground for their convictions.

In one sense, however, Hamann can certainly be seen as a critic—or metacritic—of the Enlightenment. The question of what ‘Enlightenment’ consists in was a challenge Hamann through down to his contemporaries, from his debut with Socratic Memorabilia (1759) to the end of his life. It is instructive to juxtapose Kant's famous essay “An Answer to the Question: What is Enlightenment?” (1784) with Hamann's response in a letter to his acquaintance Christian Jacob Kraus. Kant defines enlightenment as the exit from ‘self-incurred minority’ (or ‘immaturity’ or ‘tutelage’), which arises from laziness and cowardice. (The ‘entire fairer sex’ in particular is said by Kant to regard the transition to maturity and thinking for oneself as difficult and dangerous). ‘*Sapere aude*!’ (‘Dare to know!’), Kant instructs the reader. However, while Kant urges the ‘public’ use of reason (use of reason as a scholar), he nevertheless claims that ‘private’ (we would perhaps say, ‘professional’) use of reason must be circumscribed, for example, for the clergyman, soldier, or taxpayer; they must simply obey. Moreover, Kant heaps praise on their monarch, Frederick the Great, whom Hamann deemed immoral and despotic.

The irony of being instructed to think for oneself, and being told to have the courage to know, was not lost on Hamann. More painful is the irony in being told to appreciate the freedom to think, but “believe, march, pay if the devil is not to take you” (Hamann's depiction of Kant's insistence that clergymen, soldiers and taxpayers must just obey orders). “What good to me is the festive garment of freedom when I am in a slave's smock at home?” Hamann asks, referring to Kant's approval of public use of reason but ‘private’ requirement to obey. In Hamann's view, the scholarly freedom to reflect, which Kant commends, is a luxury compared to the ethical imperative to question and debate in the professional and political sphere, which Kant restricts. “Thus the public use of reason and freedom is nothing but a dessert, a

sumptuous dessert. The private use is the *daily bread* that we should give up for its sake. The *self-incurred immaturity* is just such a sneer as he makes at the whole fair sex, and which my three daughters will not put up with.”

Most urgently, therefore, Hamann objects to the allegation that this immaturity is ‘self-incurred’, rather than imposed on the people firstly by a despotic monarch, and secondly by intellectuals like Kant, with the ‘prattle and reasoning of those emancipated immature ones, who set themselves up as guardians’. ‘*True enlightenment*,’ Hamann concludes sarcastically, with an eye to the likes of Kant and Frederick, “consists in an emergence of the immature person from a supremely *self-incurred guardianship*.”

8. Language

Language is one of Hamann's most abiding philosophical concerns. From the beginning of his work, Hamann championed the priority which expression and communication, passion and symbol possess over abstraction, analysis and logic in matters of language. Neither logic nor even representation (in Rorty's sense) possesses the rights of the first-born. Representation is secondary and derivative rather than the whole function of language. Symbolism, imagery, metaphor have primacy; “Poetry is the mother-tongue of the human race.” (N II, 197) To think that language is essentially a passive system of signs for communicating thoughts is to deal a deathblow to true language.

For all Hamann's emphasis in his earlier writings on passion and emotion, he does not equate language with emotional expression. This became clear in his engagement with the writing of his younger friend Herder on the origin of language. Language has a mediating relationship between our reflection, one another, and our world; and as it is not simply the cries of emotion of an animal, so too it is not a smothering curtain between us and the rest of reality. Language also has a mediating role between God and us. Hamann's answer to a debate of his time, the origin of language — divine or human?—is that its origin is found in the relationship between God and humanity. Typically he has the ‘Knight of the Rose-Cross’ express this in the form of a ‘myth’, rather than attempting to work out such a claim logically and systematically. Rewriting the story of the Garden of Eden, he describes this paradise as:

> Every phenomenon of nature was a word,—the sign, symbol and pledge of a new, mysterious, inexpressible but all the more intimate union, participation and community of divine energies and ideas. Everything the human being heard from the beginning, saw with its eyes, looked upon and touched with its hands was a living word; for God was the word.(NIII, 32: 21-30)

This makes the origin of language as easy and natural as child's play.

By the end of his life, because of his engagement with Kant, the most urgent question among the relationships that constitute language is the relationship of language to thinking or ‘reason’. In his view, the central question of Kant's first *Critique*, the very possibility of *a priori* knowledge and of pure reason, depends on the nature of language. In a passage full of subtle allusions to Kantian passages and terms, he

writes:

> Indeed, if a chief question does remain: *how is the power to think possible?*—The power to think *right* and *left, before* and *without, with* and *above* experience? then it does not take a deduction to prove the genealogical priority of language…. Not only the entire ability to think rests on language... but language is also the *crux of the misunderstanding of reason with itself*. (N III, 286:1-10)

Critique creates.

For Hamann, in contrast to Kant, the question is therefore not so much 'what is reason?' as 'what is language?', as he writes in a letter. This is the ground of the paralogisms and antinomies that Kant raises in his Critique. Sharing Hume's empiricism and Berkeley's suspicion of universals and abstract terms, he concludes: "Hence it happens that one takes *words* for *concepts*, and *concepts* for the *things themselves*." (ZH 5, 264:34-265:1) Language then has a fundamental role to play in unmasking the philosopher's tendency to 'prosopopoeia'. The relation of language to reason he certainly did not feel had solved, however, as he wrote to a friend:

> If only I was as eloquent as Demosthenes, I would have to do no more than repeat a single word three times. Reason is language—Logos; I gnaw on this marrowbone and will gnaw myself to death over it. It is still always dark over these depths for me: I am still always awaiting an apocalyptic angel with a key to this abyss. (ZH 5, 177:16-21)

9. Knowledge

For Hamann, knowledge is inseparable from self-knowledge, and self-knowledge inseparable from knowledge of the other. We are visible, as in a mirror, in each other; 'God and my neighbor are therefore a part of my self-knowledge, my self-love.' (N I, 302:16-23) He writes in a letter: "Self knowledge begins with the neighbor, the mirror, and just the same with true self-love; that goes from the mirror to the matter." (ZH 6, 281:16-17) Sometimes this exploration of self-knowledge through interpersonal intimacy takes a sexual form, as in the Sibyl's Essay on Marriage (already discussed).

All forms of knowledge, of learning and development even of the most natural functions, require the help of another. (The 'Knight of the Rose Cross', while jesting with Hume, tells us ironically that even eating and drinking, and indeed excretion, are not instinctual or innate but require teaching.) (N III, 28:26-28; N III, 29:7-10) This is conceived not only in such immediately interpersonal ways, but also more widely in the context of the community. The indispensability of 'the other' for knowledge is also the reason that Hamann gives the importance he does to tradition in the formation of knowledge. "Our reason arises, at the very least, from this twofold lesson of sensuous revelations and human testimonies". (N III 29:28-30) Years before Kant's first *Critique*, Hamann attempts to relate the senses and the understanding and their roles in knowledge, using a characteristically concrete metaphor: the senses are like the stomach, the understanding like blood vessels. Not only do the blood vessels need the stomach to receive the

nourishment that they distribute; the stomach also needs the blood vessels to function. This insistence on the mutual dependency and interrelation of sense experience and understanding (as opposed to many Enlightenment views that plumped for either reason or the senses as the dominant party) was refined in his engagement with Kant's critique. Throughout his life, he was neither materialist, purely empiricist or positivist, nor idealist, rationalist or intellectualist in his epistemology. Rather, he is firmly against dividing knowledge or ways of knowing into different kinds. “The philosophers have always given truth a bill of divorce, by separating what nature has joined together and vice versa”. (N III, 40: 3-5) With Kant's critique, the problem becomes still more urgent; Kant's treatment of the issue is a “violent, unwarranted, obstinate divorce of what nature has joined together”. Revising Kant's metaphor of sensibility and understanding as two stems of human knowledge, he suggests we see knowledge as a single stem with two roots. Thus he rejects the division of what can be known *a priori* from what can be known a posteriori, and many of the consequences of such a stance. Here again he reaches for the ‘Principle of the Union of Opposites’ in his deployment of imagery to suggest a different approach. The relation of the senses and understanding is a ‘hypostatic union’, a ‘*communicatio idiomatum*’ (phrases borrowed from Christian theological discussion of how the two natures of divine and human are united in Christ). This mysterious union can only be revealed and understood by ‘ordinary language’. (In suggesting that the problems in philosophy can be cured by attending to ‘ordinary language’, he clearly anticipates the late Wittgenstein).

In this engagement with Kant, Hamann returns and deepens the lesson he had learnt much earlier in his reading of Hume: that belief or faith is an essential precursor for knowledge. Everything is dependent or grounded on faith; there is no privileged position for any kind or form of knowledge (a priori, scientific, etc.) In Hamann's epistemology, the hard division between ‘knowledge’ and ‘belief’ or ‘faith’ becomes eroded. Both knowledge and faith rest on a foundation of trust; neither rest on a foundation of indubitability. “Every philosophy consists of certain and uncertain knowledge, of idealism and realism, of sensuousness and deductions. Why should only the uncertain be called belief? What then are—*rational grounds?*” (ZH 7, 165:33-37) ‘Sensuousness’ translates *Sinnlichkeit* (Kant's ‘sensibility’). Belief and reason both need each other; idealism and realism are a fantasized opposition, of which the authentic use of reason knows nothing. The unity that lies in the nature of things should lie at the foundation of all our concepts and reflection. (ZH 7, 165:7-17)

10. Interpretation and Understanding

From his ‘debut’ work, *Socratic Memorabilia*, Hamann began to promulgate a particular view of what it means to understand something. From the beginning of that essay he emphasized the importance of passion and commitment in interpretation; undermining the more conventional assumption that objectivity and detachment are prerequisites of philosophical reflection and understanding. In *Aesthetica in Nuce*, wearing the authorial mask of the ‘kabbalistic philologian’, he provocatively maintained that initiation into orgies were necessary before the interpreter could safely begin the hermeneutical act. The idea that one must rid oneself of presuppositions, prejudices, and predilections in order to do justice to the subject matter he characterizes as ‘monastic rules’—i.e. an excessive asceticism and abstinence. He goes so far as to compare such individuals to self-castrating eunuchs. (N II, 207:10-20)

Hamann's skepticism about neutrality and objectivity does not make him a ‘subjectivist’, however. The stance and disposition of the interpreter is integral, helpful, indeed, indispensable and must be acknowledged; but limitless subjectivity arouses Hamann's scorn. Those who ‘flood the text’ with glosses and marginalia, “dreaming up one's own inspiration and interpretation,” Hamann likens to the blind leading the blind. (N II, 208:3ff.)

The constraints which Hamann places on the interpreter's subjectivity are not those usually advocated, therefore: an avoidance of prejudice and pre-conceptions; an amnesia for one's own history, tradition and culture; an obedience to exegetical rules. The first restraint on subjective distortion is the interpreter's own common sense; the last is the reaction of the text itself: “what are you trying to make of me?” The interpreter's freedom is inextricable from the interpreter's respect and responsibility, in Hamann's view.

The responsible interpreter is conscious of standing within something larger than oneself: a tradition. The wise interpreter is a kabbalist, one who interprets an ancient text, and a rhapsodist—the original meaning of the latter being one who stitches something together from pre-existing materials. (In Ancient Greece the ‘rhapsodist’ was one who recited poems cobbled together from prior sources, usually bits of Homer.) In creating interpretations, the interpreter enjoys the freedom to create anew, as Hamann created his characteristic prose from pre-existing texts, while creating a new meaningful piece. Hamann's use of this genre itself makes the point: the demand that only one meaning may exist for a text arises from an impoverished notion of meaning and creativity; one that misunderstands the nature of composition and the nature of interpretation alike.

Hamann's rejected both exegetical ‘materialism’ and ‘idealism’, as he called them — literalism and excessive flights of fancy. In thus insisting on the integrity of ‘the letter *and* the spirit’, he means to preserve the place of author, text and reader alike. Both meaning and interpretation rest in a three-way relationship.

For Hamann, the depth and meaning of a text go beyond the author's own contribution, and are the responsibility of the interpreter: “Few authors understand themselves, and a proper reader must not only *understand* his author but also be able to *see beyond him*.” (ZH 6, 22:10-12) And yet this recognition that the author's opinions and intentions do not exhaust the possibilities of the text does not annihilate the place of the author. At the very least, the ‘beyond’ of the text includes a territory which, if unknown to the author, is not unrelated: that is, the author's own unconscious workings and meanings. It is not accidental that Hamann observes *not* that few authors understand their own *text,* but that few authors understand *themselves*. This suggests a picture of creation in which more of the author is expressed in a text and entrusted to the interpreter than the author's conscious intentions and opinions. This in turn suggests a picture of interpretation—of “understanding one's hero” as Hamann put it when writing about Socrates—in which greater sensitivity, insight, and fidelity is demanded of the interpreter than would otherwise be the case. Above all, the interpreter must have the courage to be a kabbalist; that is, to say more than the text does, not to express oneself but to say what the author left unsaid. The fruits of such faithful creativity may be impossible to ‘justify’ or ‘verify’ to the demands of the objectivist, however.

Fundamentally, for Hamann hermeneutics consists in perceiving the underlying relationship beneath the phenomenon in question; at the least, of course, the relationship between the author and the interpreter which requires such fidelity. Given Hamann's religious views, this at once introduces a theological dimension. Ultimately, this means that for Hamann proper hermeneutics rests on one thing: perceiving God revealed within the phenomenon, whether that be nature or history (cf. *Socratic Memorabilia* and *Aesthetica in Nuce* for examples). Even the interpretation of ourselves is a revelation of God; a recognition of whose image solves all the most complicated knots and riddles of our nature. (N II, 206:32-207:2; 198:3-5)

11. Humanity

The topics examined so far all have their anthropological implications. Hamann's critique of the socio-political implications of Kant's vision of ‘enlightenment’ rests on a conviction about our social and political destiny. Hamann sees our socio-political vocation as consisting firstly in ‘criticism’ (or ‘critique’)—recognizing and appropriating, or hating and rejecting, the true vs. the false, good vs. evil, beautiful vs. ugly; and secondly in ‘politics’, which is increasing or reducing them. This is not the prerogative of the ruler; every one is at once their own ‘king’, their own ‘legislator’; but also the ‘first-born of their subjects’. It is our “republican privilege” to contribute to this destiny, “the critical and magisterial office of a political animal.” (N III, 38-39)

The concepts of knowledge and language and their many facets also imply a particular anthropology: the diversity yet integration of the human being. For Hamann, the truest picture of humanity is of diversity in unity; a number of different, often contrasting aspects and features together composing the human person. Hamann consequently did not confine his attention to epistemology and reason when considering what human beings are, and passion, the thirst for vengeance, and sexual ecstasy form a part of his picture as well. (In response to the Enlightenment aesthetic of art as the imitation of ‘beautiful nature’, Hamann's ironic observation was: “The thirst for vengeance was the beautiful nature which Homer imitated.” ZH 2, 157:12)

The theme of interdependence between human beings, which was emphasized in his epistemology, also has its roots in his understanding of what it is to be human. We are not self-sufficient; but for Hamann, even our lacks and failings have a positive thrust, this signifier of dependency making us all the more suited for the enjoyment of nature and one another.

If there is a fundamental key to his thinking on humanity, it is the idea that the human being is the image of God. This is admittedly more theological than philosophical, but is essential for understanding Hamann's philosophical anthropology. Hamann's treatment of this perennial theme is hardly conventional in the history of Christian thinking. While the experience of sinfulness and wickedness is a powerful theme, particularly in his earlier, post-conversion writing, the fundamental thrust of his thinking is the easy exchange between the human and the divine. In this exchange, language is “the sign, symbol and pledge of a new, mysterious, inexpressible but all the more intimate union, participation and community of divine energies and ideas.“ (N III, 32:21-24) Despite his reputation for being an irrationalist, reasoning

too relates us to God; God, nature and reason are described as having the same relation as light, the eye and what we see, or as author, text and reader. (ZH 5, 272:14-16)

One must also remember that Hamann confessed that he could not conceive of a Creative Spirit without genitalia; indeed, he was quite happy to assert that the genitals are the unique bond between creature and Creator. So sexuality in divine-human relations has two aspects. First, as paradigm of creativity, it is the way in which our God-likeness can most strikingly be seen. Secondly, as the point of the most profound unity, it is the locus for our union both with another human being and with the divine. Provocatively, Hamann sees original sin and its rebellion as embodied not in sexuality, but in reason. Overweening reason is our attempt to be like God; meanwhile, prudery is the rejection of God's image, while trying to be like God in the wrong sense (bodilessness). (See Essay of a Sibyl on Marriage and Konxompax.) One should therefore distinguish ‘likeness to God’ from ‘being equal to God’. In the Sibyl's essay, the male version of grasping at equality with God (cf. Phil. 2:6) is the attempt to be self-sufficient, to be the God of monotheism: the sole ruler, who possesses self-existence. Instead, the encounter with the opposite sex should engender in the man an attitude of profound respect towards the woman's body, as the source of his own existence, from his mother. As the source of his own joy, lovemaking also is an acknowledgement of his own dependence, his lack of self-sufficiency and autonomy. But this dependence on another paradoxically is the Godlikeness of the Creator, the father, the one who humbles himself in self-giving (a favourite Hamannian theme in his discussion of God). Meanwhile, the woman's temptation is to an artificial innocence; a secret envy of God's incorporeality and impassibility. The defence of one's virginity is another cryptic attempt at self-sufficiency. Instead, the woman must brave the ‘tongues of fire’ in a ‘sacrifical offering of innocence’, in order to realize her Godlikeness; which is not to be found in bodilessness and the absence of passion, but in passionate creativity; in the willingness to be incarnate. Thus, if human beings are in the image of God, it is a trinitarian image of God, a mutual relation of love of ‘Father’, ‘Son’ and ‘Spirit’; found in creating, in saving, and in tongues of fire.

Bibliography

Hamann's writings

Hamann's works, including those unpublished in his lifetime, are reprinted in the collection edited by Josef Nadler:

- Hamann, Johann Georg. *Sämtliche Werken*, edited by Josef Nadler. 6 volumes. Vienna: Verlag Herder, 1949-1957). This was reprinted recently by Brockhaus in Wuppertal, 1999.

Citations from this source, in conformity with common practice for Hamann references, are given above as: N II, 13:10. This means “Nadler's edition, volume two, page thirteen, line ten.” This same mode of reference also applies to the translations in Gwen Griffith Dickson (see below), wherein the pages are laid out in as close an approximation as possible to Nadler's edition.

Hamann's Letters

- Hamann, Johann Georg. *Briefwechsel*, edited by Walther Ziesemer and Arthur Henkel (from volume 4 on, edited by Henkel alone). 8 volumes. Wiesbaden/ Frankfurt: Insel Verlag, 1955-1975.

Citations from this source are given as: ZH 4 etc. as above.

All translations from Hamann's works and letters in the above article are from Gwen Griffith Dickson (see below) except for the translation from the letter to Kraus, which is cited in the translation by Garrett Green, in Schmidt, James (ed.). What is Enlightenment? Eighteenth-Century Answers and Twentieth-Century Questions. Berkeley and Los Angeles: University of California Press, 1996.

Other selections

- Johann Georg Hamann. *Schriften zur Sprache. Einleitung und Anmerkungen von Josef Simon*. Frankfurt a.M.: Suhrkamp Verlag 1967. (suhrkamp theorie 1).

Richard Rorty

Richard Rorty's distinctive and controversial brand of pragmatism expresses itself along two main axes. One is negative---a critical diagnosis of what Rorty takes to be defining projects of modern philosophy. The other is positive---an attempt to show what intellectual culture might look like, once we free ourselves from the governing metaphors of mind and knowledge in which the traditional problems of epistemology and metaphysics (and indeed, in Rorty's view, the self-conception of modern philosophy) are rooted. The centerpiece of Rorty's critique is the provocative account offered in *Philosophy and the Mirror of Nature* (1979, hereafter PMN). In this book, and in the closely related essays collected in *Consequences of Pragmatism* (1982, hereafter CP), Rorty's principal target is the philosophical idea of knowledge as representation, as a mental mirroring of a mind-external world. Providing a contrasting image of philosophy, Rorty has sought to integrate and apply the milestone achievements of Dewey, Hegel and Darwin in a pragmatist synthesis of historicism and naturalism. Characterizations and illustrations of a post-epistemological intellectual culture, present in both PMN (part III) and CP (xxxvii-xliv), are more richly developed in later works, such as *Contingency, Irony, and Solidarity* (1989, hereafter CIS) and in the three volumes of philosophical papers, *Objectivity, Relativism, and Truth* (1991, hereafter ORT); *Essays on Heidegger and Others* (1991, hereafter EHO); and *Truth and Progress* (1998, hereafter TP). In these writings, ranging over an unusually wide intellectual territory, Rorty offers a highly integrated, multifaceted view of thought, culture, and politics which has made him one of the most widely discussed philosophers writing today.

---

1. Biographical Sketch

Richard Rorty was born on October 4th, 1931, in New York City. He grew up, as he recounts in *Achieving Our Country* (1998, hereafter AC), "on the anti-communist reformist Left in mid-century" (AC

59), within a circle combining anti-Stalinism with leftist social activism. "In that circle," Rorty tells us, "American patriotism, redistributionist economics, anticommunism, and Deweyan pragmatism went together easily and naturally." (AC 61) In 1946 Rorty went to the University of Chicago, to a philosophy department which at that time included Rudolph Carnap, Charles Hartshorne, and Richard McKeon, all of whom were Rorty's teachers. After receiving his BA in 1949, Rorty stayed on at Chicago to complete an M.A. (1952) with a thesis on Whitehead supervised by Hartshorne. From 1952 to 1956 Rorty was at Yale, where he wrote a dissertation entitled "The Concept of Potentiality." His supervisor was Paul Weiss. After the completion of his Ph.D., followed by two years in the army, Rorty received his first academic appointment, at Wellesley College. In 1961, after three years at Wellesley, Rorty moved to Princeton University where he stayed until he went to the University of Virginia, in 1982, as Kenan Professor of the Humanities. Rorty left the University of Virginia in 1998, accepting an appointment in the Department of Comparative Literature at Stanford University. In the course of his career, Rorty has received several academic awards and honours, including a Guggenheim Fellowship (1973-74) and a MacArthur Fellowship (1981-1986). He has held a number of prestigious lectureships, giving, among others, the Northcliffe Lectures at University College, London (1986), the Clark Lectures at Trinity College, Cambridge (1987), and the Massey Lectures at Harvard (1997).

2. Against Epistemology

On Rorty's account, modern epistemology is not only an attempt to legitimate our claim to knowledge of what is real, but also an attempt to legitimate philosophical reflection itself--a pressing task, on many accounts, once the advent of the new science gradually gave content to a notion of knowledge obtained by the methodological interrogation of nature herself. Because the result of this kind of interrogation, theoretical empirical knowledge, is so obviously fruitful, and also carries with it seemingly uncontentious norms of progress, its mere presence poses a legitimation challenge to a form of thought, and claim to knowledge, that is distinct from it. Cartesian epistemology, in Rorty's picture, is designed to meet this challenge. It is sceptical in a fundamental way; sceptical doubts of a Cartesian sort, that is, doubts that can be raised about any set of empirical claims whatever, and so cannot be alleviated by experience, are tailor-made to preserve at once a domain and a job for philosophical reflection. Rorty's aim in PMN is to undermine the assumptions in light of which this double legitimation project makes sense.

2.1 Epistemological Behaviorism

That any vocabulary is optional and mutable is the basic conviction behind Rorty's attack on representationalist epistemology carried out in PMN. It informs, for instance, the genealogy (chapter one) and deconstruction (chapter two) of the concept of mind offered in the book's first part, "Our Glassy Essence." This historicist conviction, however, is not itself a central theme of PMN, and it emerges for

explicit discussion only in the final section of the book, "Philosophy," which is the shortest and in some ways least developed of its three parts. The argumentative core of PMN is found in its second part, "Mirroring". Here Rorty develops and extends a diverse lot of arguments--notably from Wilfrid Sellars, Willard Van Orman Quine, Thomas Kuhn, Ludwig Wittgenstein, and Donald Davidson--into a general critique of the defining project of modern epistemology, viz. the conceptions of mind, of knowledge and of philosophy bequeathed by the 17th and 18th centuries. Rorty's key claim is that "the Kantian picture of concepts and intuitions getting together to produce knowledge is needed to give sense to the idea of 'theory of knowledge' as a specifically philosophical discipline, distinct from psychology." (PMN 168). According to Rorty,

> This is equivalent to saying that if we do not have the distinction between what is "given" and what is "added by the mind," or that between the "contingent" (because influenced by what is given) and the necessary (because entirely "within" the mind and under its control), then we will not know what would count as a "rational reconstruction" of our knowledge. We will not know what epistemology's goal or method could be. (PMN 168-9)

Epistemology, in Rorty's account, is wedded to a picture of mind's structure working on empirical content to produce in itself items--thoughts, representations--which, when things go well, correctly mirror reality. To loosen the grip of this picture on our thinking is to challenge the idea that epistemology--whether traditional Cartesian or 20th century linguistic--is the essence of philosophy. To this end, Rorty combines a reading of Quine's attack on a version of the structure-content distinction in "Two Dogmas of Empiricism" (1952), with a reading of Sellars' attack on the idea of givenness in "Empiricism and the Philosophy of Mind" (1956/1997). On Rorty's reading, though neither Sellars nor Quine is able fully to take in the liberating influence of the other, they are really attacking the same distinction, or set of distinctions. While Quine casts doubt on the notion of structure or meaning which linguistically-turned epistemology had instated in place of mental entities, Sellars, questioning the very idea of givenness, came at the distinction from the other side:

> ...Sellars and Quine invoke the same argument, one which bears equally against the given-versus-nongiven and the necessary-versus-contingent distinctions. The crucial premise of this argument is that we understand knowledge when we understand the social justification of belief, and thus have no need to view it as accuracy of representation. (PMN 170)

The upshot of Quine's and Sellars' criticisms of the myths and dogmas of epistemology is, Rorty suggests, that "we see knowledge as a matter of conversation and of social practice, rather than as an attempt to mirror nature." (PMN 171) Rorty provides this view with a label: "Explaining rationality and epistemic authority by reference to what society lets us say, rather than the latter by the former, is the essence of what I shall call 'epistemological behaviorism,' an attitude common to Dewey and Wittgenstein." (PMN 174)

Epistemological behaviorism leaves no room for the kind of practice-transcending legitimation that Rorty identifies as the defining aspiration of modern epistemology. Assuming that epistemic practices do, or at least can, diverge, it is not surprising that Rorty's commitment to epistemological behaviorism should lead

to charges of relativism or subjectivism. Indeed, many who share Rorty's historicist scepticism toward the transcending ambitions of epistemology--friendly critics like Hilary Putnam, John McDowell and Daniel Dennett--balk at the idea that there are no constraints on knowledge save conversational ones. Yet this is a central part of Rorty's position, repeated and elaborated as recently as in TP. Indeed, he invokes it there precisely in order to deflect this sort of criticism. In "Hilary Putnam and the Relativist Menace," Rorty says:

> In short, my strategy for escaping the self-referential difficulties into which "the Relativist" keeps getting himself is to move everything over from epistemology and metaphysics into cultural politics, from claims to knowledge and appeals to self-evidence to suggestions about what we should try. (TP 57)

That epistemological behaviorism differs from traditional forms of relativism and subjectivism is easier to see in light of Rorty's criticism of the notion of representation, and the cluster of philosophical images which surround it.

2.2 Antirepresentationalism

Rorty's enduring attitude to relativism and subjectivism is that both are products of the representationalist paradigm. Though the theme is explicit in PM and CP ("Pragmatism, Relativism, Irrationalism"), it is with Rorty's later and further appropriation of Davidson that his criticism of the idea of knowledge as representation becomes fully elaborated (ORT "Introduction" and Part II). Drawing on Davidson's criticism of the scheme-content distinction ("On the Very Idea of a Conceptual Scheme") and of the correspondence theory of truth ("The Structure and Content of Truth"), Rorty is able to back up his rejection of any philosophical position or project which attempts to draw a general line between what is made and what is found, what is subjective and what is objective, what is mere appearance and what is real. Rorty's position is not that these conceptual contrasts never have application, but that such application is always context and interest bound and that there is, as in the case of the related notion of truth, nothing to be said about them in general. Rorty's commitment to the conversationalist view of knowledge must therefore be distinguished from subjectivism or relativism, which, Rorty argues, presuppose the very distinctions he seeks to reject. Equally, Rorty's epistemological behaviorism must not be confused with an idealism that asserts a primacy of thought or language with respect to the unmediated world, since this, too, is a position that is undercut by Rorty's Davidsonian position. In light of the view of truth and of meaning that Rorty appropriates from Davidson, his conversationalism is not a matter of giving priority to the subjective over the objective, or to mind's power over world's constraint. Rather it is the other side of his anti-representationalism, which denies that we are related to the world in something other than causal terms. Differently put, Rorty argues that we can give no useful content to the notion that the world, by its very nature, rationally constrains choices of vocabulary with which to cope with it. (TP "The Very Idea of Human Answerability to the World: John McDowell's Version of Empiricism").

2.3 Rationality, Science, and Truth

Attacking the idea that we must acknowledge the world's normative constraint on our belief-systems if we are to be rational subjects, Rorty has drawn a great deal of criticism that takes science, particularly natural science, as its chief reference point. Two general kinds of criticisms are often raised. The first insists that science consists precisely in the effort to learn the truth about how things are by methodically allowing us to be constrained in our beliefs by the world. On this view, Rorty is simply denying the very idea of science. The other kind of criticism seeks to be internal: if Rorty's view of science were to prevail, scientists would no longer be motivated to carry on as they are; science would cease to be the useful sort of thing that Rorty also thinks it is (see, eg., Bernard Williams, "Auto da Fe" in Malachowski). However, Rorty's view of science is more complicated than he himself sometimes implies. He says: "I tend to view natural science as in the business of controlling and predicting things, and as largely useless for philosophical purposes." ("Reply to Hartshorne," Saatkamp 32) Yet he spends a good deal of time drawing an alternative picture of the intellectual virtues that good science embodies (ORT Part I). This is a picture which eschews the notion that science succeeds, when it does, in virtue of being in touch with reality in a special way, the sort of way that epistemologists, when successful, can clarify. It is in this sense specifically that Rorty disavows science as philosophically significant. Good science may nevertheless be a model of rationality, in Rorty's view, exactly in so far as scientific practice has succeeded in establishing institutions conducive to democratic exchange of view.
